4. TITLE AND SUBTITLE TAMI Model Programmer's Guide Volume II		5. FUNDING NUMBERS DCA100-91-C-0015		
6. AUTHOR(S) Andre Rausch				
7. PERFORMING ORGANIZATION NAME(S) AND ADDRESS(ES) Booz, Allen & Hamilton, Inc. 8283 Greensboro Drive McLean, Virginia 22102		8. PERFORMING ORGANIZATION REPORT NUMBER		
9. SPONSORING/MONITORING AGENCY NAME(S) AND ADDRESS(ES) National Communications System Office of Technology and Standards Division 701 South Court House Road Arlington, Virginia 22204-2198		10. SPONSORING/MONITORING AGENCY REPORT NUMBER NCS TIB #95-4 VOL II		
11. SUPPLEMENTARY NOTES				
12a. DISTRIBUTION/AVAILABILITY STATEMENT Approved for public release; distribution is unlimited.		12b. DISTRIBUTION CODE		
13. ABSTRACT (Maximum 200 words) As part of the ongoing effort to analyze the performance of the public switched network (PSN) and the programs of the National Level National Security and Emergency Preparedness (NS/EP) Telecommunications Program (NLP), Office of Technology and Standards Division (N6) has developed a number of computer-based models. The Traffic Analysis by Method of Iteration (TAMI) model was developed to measure the effects of telecommunications traffic congestion in stressed local and long distance networks. This document provides the second of two volumes of the TAMI Programmer's Manual. These volumes provide the software description necessary for a programmer to support future maintenance and enhancements to the TAMI model. This volume documents the remaining 12 modules. It is assumed that the reader has a basic understanding of the PSN and a working knowledge of the architectures of the three major inter-exchange carrier networks (IEC) and the local exchange carrier networks (LEC). A programmer using TAMI should have a working knowledge of the UNIX operating system and the 'C' and FORTRAN programming languages. A background in voice teletraffic engineering and analytical modeling and simulation is desirable.

GENERAL INSTRUCTIONS FOR COMPLETING SF 298

The Report Documentation Page (RDP) is used in announcing and cataloging reports. It is important that this information be consistent with the rest of the report, particularly the cover and title page. Instructions for filling in each block of the form follow. It is important to *stay within the lines* to meet *optical scanning requirements*.

Block 1. Agency Use Only (Leave blank).

Block 2. Report Date. Full publication date including day, month, and year, if available (e.g. 1 Jan 88). Must cite at least the year.

Block 3. Type of Report and Dates Covered. State whether report is interim, final, etc. If applicable, enter inclusive report dates (e.g. 10 Jun 87 - 30 Jun 88).

Block 4. Title and Subtitle. A title is taken from the part of the report that provides the most meaningful and complete information. When a report is prepared in more than one volume, repeat the primary title, add volume number, and include subtitle for the specific volume. On classified documents enter the title classification in parentheses.

Block 5. Funding Numbers. To include contract and grant numbers; may include program element number(s), project number(s), task number(s), and work unit number(s). Use the following labels:

C - Contract	PR - Project
G - Grant	TA - Task
PE - Program Element	WU - Work Unit Accession No.

Block 6. Author(s). Name(s) of person(s) responsible for writing the report, performing the research, or credited with the content of the report. If editor or compiler, this should follow the name(s).

Block 7. Performing Organization Name(s) and Address(es). Self-explanatory.

Block 8. Performing Organization Report Number. Enter the unique alphanumeric report number(s) assigned by the organization performing the report.

Block 9. Sponsoring/Monitoring Agency Name(s) and Address(es). Self-explanatory.

Block 10. Sponsoring/Monitoring Agency Report Number. (If known)

Block 11. Supplementary Notes. Enter information not included elsewhere such as: Prepared in cooperation with...; Trans. of...; To be published in.... When a report is revised, include a statement whether the new report supersedes or supplements the older report.

Block 12a. Distribution/Availability Statement. Denotes public availability or limitations. Cite any availability to the public. Enter additional limitations or special markings in all capitals (e.g. NOFORN, REL, ITAR).

DOD - See DoDD 5230.24, "Distribution Statements on Technical Documents."

DOE - See authorities.

NASA - See Handbook NHB 2200.2.

NTIS - Leave blank.

Block 12b. Distribution Code.

DOD - Leave blank.

DOE - Enter DOE distribution categories from the Standard Distribution for Unclassified Scientific and Technical Reports.

NASA - Leave blank.

NTIS - Leave blank.

Block 13. Abstract. Include a brief (*Maximum 200 words*) factual summary of the most significant information contained in the report.

Block 14. Subject Terms. Keywords or phrases identifying major subjects in the report.

Block 15. Number of Pages. Enter the total number of pages.

Block 16. Price Code. Enter appropriate price code (*NTIS only*).

Blocks 17. - 19. Security Classifications. Self-explanatory. Enter U.S. Security Classification in accordance with U.S. Security Regulations (i.e., UNCLASSIFIED). If form contains classified information, stamp classification on the top and bottom of the page.

Block 20. Limitation of Abstract. This block must be completed to assign a limitation to the abstract. Enter either UL (unlimited) or SAR (same as report). An entry in this block is necessary if the abstract is to be limited. If blank, the abstract is assumed to be unlimited.

FOREWORD

The National Communications System (NCS) is an organization of the Federal Government whose membership is comprised of 23 Government entities. Its mission is to assist the President, National Security Council, Office of Science and Technology Policy, and Office of Management and Budget in:

- o The exercise of their wartime and non-wartime emergency functions and their planning and oversight responsibilities.
- o The coordination of the planning for and provisions of National Security/Emergency Preparedness communications for the Federal Government under all circumstances including crisis or emergency.

In support of this mission, the NCS has conducted studies and analyses to assess the potential for serious damage to portions of the Nation's telecommunications infrastructure due to various threats. The purpose of the work is to provide guidance to programmers on the TAMI module structure.

Comments on this TIB are welcome and should be addressed to:

1.0 Introduction

The Office of the Manager, National Communications System (OMNCS) Office of Technology and Standards (NT) is responsible for a broad range of initiatives including Federal telecommunications standards development, network performance analyses, and technology review. As part of the ongoing effort to analyze the performance of the public switched network (PSN) and the programs of the National Level National Security and Emergency Preparedness (NS/EP) Telecommunications Program (NLP), NT has developed a number of computer-based models. Most recently, the Traffic Analysis by Method of Iteration (TAMI) model was developed to measure the effects of telecommunications traffic congestion in stressed local and long distance networks.

1.1 Purpose

This document provides the second of two volumes of the TAMI Programmer's Manual. Together, these volumes provide the software description necessary for a programmer to support future maintenance and enhancements to the TAMI model.

1.2 Scope

Volume I of the TAMI Programmer's Manual documents the first 11 of 23 modules that form the TAMI model. Volume II of the TAMI Programmer's Manual, this volume, documents the remaining 12 modules. It is assumed that the reader has a basic understanding of the PSN and a working knowledge of the architectures of the three major inter-exchange carrier networks (IEC) and the local exchange carrier networks (LEC). Furthermore, a programmer using TAMI should have a working knowledge of the UNIX operating system and the 'C' and FORTRAN programming languages. A background in voice teletraffic engineering and analytical modeling and simulation is desirable to understand the algorithmic details of the TAMI model. The TAMI programmer will find it useful to be familiar with the references provided at the end of this document, which describe previous TAMI analyses, modeling concepts, algorithms, and programmer's manuals of related software.

1.3 Background

The nation's PSNs continue to be a focus of NCS modeling efforts because these networks comprise the largest, most diverse set of telecommunications assets in the United States. Furthermore, the NCS directs its NS/EP telecommunications enhancement activities toward the PSN. Additionally, most NCS member organizations rely on the PSN for conducting their NS/EP responsibilities.

The NCS has moved to measuring network performance using call completion probability in addition to connectivity because this approach captures the effects of traffic congestion. Traffic congestion is prevalent during many of the national emergencies and disasters of concern to the OMNCS.

In support of PSN traffic congestion analyses, NT has developed the TAMI model. This model measures congestion in the combined local and long-distance networks of the PSN. TAMI evaluates congestion for ordinary telephone users and for NS/EP users who benefit from planned or existing NLP enhancements. In addition to measuring nationwide congestion, the TAMI model has been expanded to model regional congestion caused by focused overloads. Focused overloads are common during events that only affect part of the country, such as earthquakes and hurricanes, during which the affected region may be subject to unusually high volumes of traffic originating from the rest of the country. As the TAMI model continues to evolve, it provides a more accurate tool for understanding the effects of congestion in the PSN.

The TAMI model has been used by both NT and the Office of Plans and Programs (NP) to measure congestion in the PSN subject to damage from electromagnetic pulse (EMP), fallout radiation, nuclear blast scenarios, and, more recently, earthquakes. An analysis has successfully been conducted to determine the sensitivity of the model's network performance results to network management and engineering assumptions made in the absence of complete PSN data. In view of continued plans to employ and enhance the TAMI model, this document provides the second of two Programmer's Manual volumes.

1.4 Organization

This report is organized into three sections. Section 1.0, this section, provides an introduction, describing the purpose, scope, background, and organization, as well as a short description of documentation conventions.

Section 2.0 provides a high level overview of the TAMI model and describes the interrelationships, dataflow, and interfaces among the twelve software modules encompassed by this report.

Section 3.0 contains detailed documentation of the remaining 12 TAMI software modules and each module's component functions.

1.5 Document Conventions

This manual documents modules and functions coded in the 'C' programming language. Throughout the manual certain conventions which may differ slightly from standard 'C' terminology have been adopted in order to more clearly describe data types, inputs, outputs and file types. In addition the typographic *courier* font is used to denote variable names.

Variable names are defined by the following conventions:

Convention	Example	Definition
character	<code>c</code>	The standard 'C' data type <i>char</i>
integer	<code>i</code>	The standard 'C' data type <i>int</i>
float	<code>real</code>	The standard 'C' data type <i>float</i>
double	<code>long_real</code>	The standard 'C' data type <i>double</i>
long integer	<code>pos</code>	The standard 'C' data type <i>long</i>
file	<code>outfile</code>	The standard 'C' data type <i>FILE</i> , a pointer to a file string
extern	<code>optarg</code>	The standard 'C' data type modifier <i>extern</i> indicating the variable is declared outside the module (e.g., the operating system)
global	<code>idx_num</code>	Variables that are declared globally accessible from any function
pointer	<code>*varname</code>	Denotes a pointer to any variable, <i>varname</i>
structure	<code>p_struct p[] with field integer p[].three</code>	The standard 'C' aggregate, heterogeneous hierarchical data structure composed of a main variable name and sub fields of multiple data types

Inputs/Outputs are defined by the following conventions:

Inputs are of two type: 1) formal inputs are passed in by the calling function; 2) global inputs are variables as defined above. Outputs are of two type: 1) formal outputs are passed out by the called function as standard 'C' returns; 2) global outputs are variables as defined above

Includes are defined by the following conventions:

Includes are of two types: 1) Standard 'C' defined function sets, e.g., `<stdio.c>`; and 2) user defined function sets, e.g., `"fileio.c"` (see Appendix A)

File formats are defined by the following conventions:

- 1) <CLLIA>, <CLLIZ>, <size>
- 2) (c11, 1x, c11, 1x, i6)

Line 1 shows the names and relative positions of the fields within each record. Line 2 shows the data type and length of each field, where:

c=character
x=space
i=integer
f=float

2.0 High Level TAMI Description

This section provides a high level overview of the TAMI Model from a software viewpoint. A number of NCS reports already exist which describe the TAMI algorithms, assumptions, and modeling techniques (References 3, 5, 6, 7). The purpose of this overview is to focus on the interrelationships, data flow, and interfaces among the software modules that constitute the TAMI model, focusing on those that were not already covered in Volume I.

The TAMI model can be divided into six main functional processes, depicted in Exhibit 2.1. Each of these processes operate on both IEC and LEC data and can be described at more detailed levels. A brief summary of the six steps is provided here:

Step 1, Pre-Process Undamaged Network and Traffic, involves developing a complete picture of the undamaged LEC and IEC networks, including physical transmission paths, sizes of logical trunk groups, and primary and alternate routing considerations. This step then involves using telco engineering methodologies to engineer peak-hour traffic over each trunk group, reverse-engineer the sizes of certain categories of trunk groups, and determine the overall end-to-end traffic.

Step 2, Generate Pool of Damage Vectors, involves deriving several random damage scenarios from a probabilistic description of a network threat. Although the original damage module used with TAMI generated EMP and Fallout Radiation damage, any module may be substituted here to derive damage for other threats such as earthquakes or hurricanes. The important point is that each version of this step performs the same basic task of translating probabilistic damage into a large pool of random possible outcomes (damage vectors) of telecommunications network damage. The Monte Carlo sampling loop can later sample these damage vectors one at a time until an average is reached within the required confidence interval.

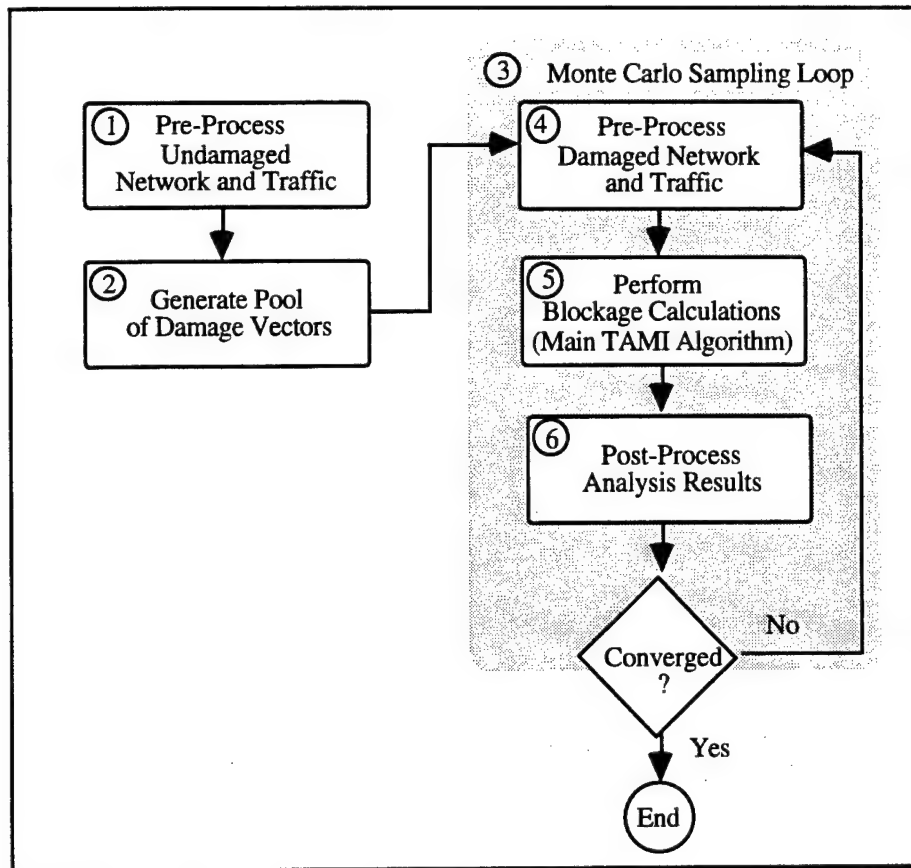

Step 3, Monte Carlo Sampling Loop, is the control loop for steps 4, 5, and 6. While these later steps each operate on only one damage vector at a time, the controlling logic in step 3 is responsible for selecting these damage vectors from the sampling pool, issuing the commands to run subsequent steps, and comparing running Monte Carlo statistics to the target confidence interval. If the target has not been reached, the Monte Carlo Sampling Loop repeats steps 4, 5, and 6 with the next damage vector in the sampling pool.

Step 4, Pre-Process Damaged Network and Traffic, involves applying the effects of a particular damage vector to the undamaged network. Trunk group sizes are set to zero where completely damaged, or adjusted appropriately where only some of the trunk group's diverse physical routes are damaged. The effects of damage on offered traffic and traffic distribution patterns are also calculated. The end result of Step 4 is a representation of both the damaged network and a damaged traffic matrix.

Step 5, Perform Blockage Calculations (Main TAMI Algorithm), is the first point where network congestion is measured for a given damage vector, using the outputs from Step 4. The post-damage traffic matrix is offered to the damaged network, and blockages are measured in each trunk group in both the LEC and IEC networks. When all the networks reach steady state, the individual trunk group blockages are combined to estimate end-to-end blockage through the PSN for that damage vector.

Step 6, Post-Process Analysis Results, is responsible for keeping the cumulative performance statistics for all damage vectors sampled so far. Therefore, every time Step 5 finishes, this step incorporates the results into its running average, increments the number of damage vectors sampled, and recomputes statistics such as variance. These statistics are examined by the controlling logic in Step 3 to determine convergence.

Exhibit 2.1
TAMI High-Level Flow Diagram

In addition to QTCM, which has been previously documented as a stand-alone model, there are 23 TAMI modules totaling an estimated 30,000 lines of code. Exhibit 2.2 categorizes each of these modules into the above six steps. It also provides the approximate lines of code for each module and indicates whether it is documented in Volume I or Volume II of the TAMI Model Programmer's Manual.

Exhibit 2.2
Table of TAMI Modules

Step #	Functional Area	Module Name	Approximate Lines of Code	Vol I	Vol II
1.0	Pre-Process Undamaged Network and Traffic IEC Networks	cg_make	200	3	
1.1		span_make	300	3

*Includes code linked from IDA/CAM model, Reference 5

As shown, Volume I encompasses Step 1.1: the pre-processing of the undamaged IEC networks and Step 2: the generation of sampling pools of EMP damage vectors. Volume II encompasses the remaining areas. While the detailed documentation for each module appears in Section 3, the remainder of this section is dedicated to describing the data flow among these modules and providing a brief description of each module, using the following subsections:

- 2.1 (Step 1.2) Pre-Process Undamaged LEC Networks and Traffic Matrix
- 2.2 (Step 3) Monte Carlo Sampling Loop
- 2.3 (Step 4.1) Pre-Process Damaged IEC Networks
- 2.4 (Step 4.2) Pre-Process Damaged LEC Networks and Traffic Matrix
- 2.5 (Step 5.1) Perform LEC Blockage Calculations
- 2.6 (Step 5.2) Perform IEC Blockage Calculations
- 2.7 (Step 6) Post-Process Analysis Results

Exhibits 2.3 through 2.5 provide a diagrammatic road map to these sections, depicting the overall data flow for AT&T, MCI, and Sprint network data through the Volume II modules. Exhibit 2.3 describes Step 1.2. Note that, while there is a different module for each IEC, the list of input files for all three modules is stored in a common 'dp.key' file. As shown, this file has a section for LEC files common to all three IECs and separate sections for each IEC. Each module uses only the files in the pertinent sections.

Exhibit 2.3 Dataflow Through Step 1.2

Because the dataflow for Step 3 and the steps controlled by it (Steps 4, 5, and 6) is so extensive, it has been divided into two diagrams, Exhibits 2.4 and 2.5. Exhibit 2.4 shows the dataflow for Steps 4.1 and 4.2, while exhibit 2.5 describes the dataflow for Steps 5 and 6. Note that Step 3 uses a key file 'tami.key.' This key file has a similar structure to the key file used in Step 1.2, including a section for the LEC and each IEC; however, some header flags have been added and there is a different set of file names in each section, including optional files and damage files. Step 3 will pass the appropriate command-line options and files from 'tami.key' to the steps that it controls.

Exhibit 2.4 Dataflow Through Steps 4.1 and 4.2

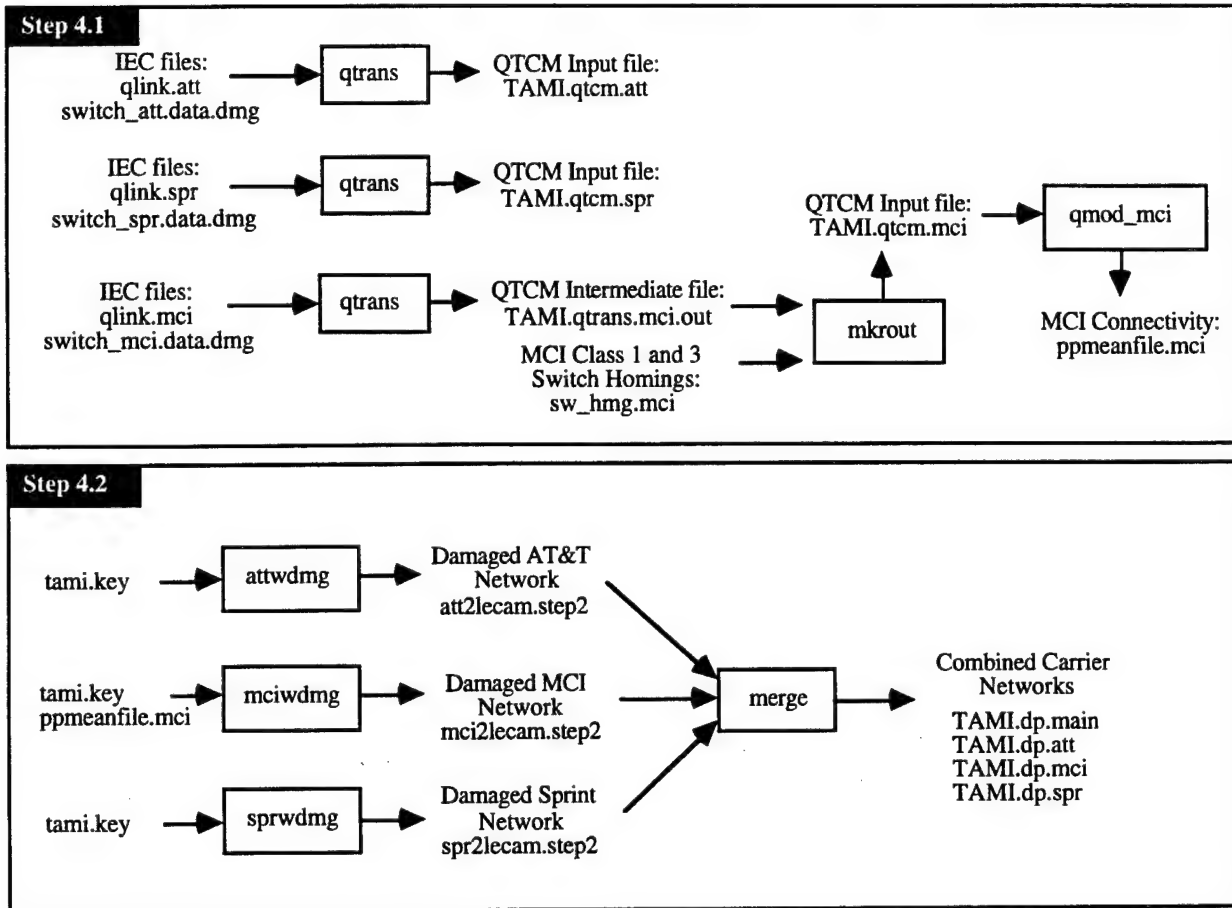

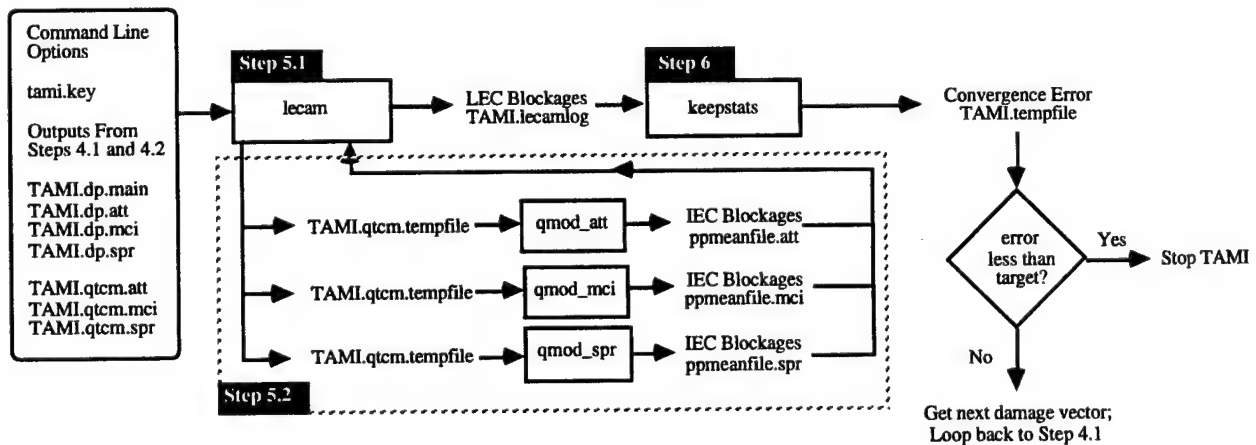

Exhibit 2.5 Dataflow Through Steps 5 and 6

2.1 (Step 1.2) Pre-Process Undamaged LEC Networks and Traffic Matrix

There are five goals to this step: (1) derive access traffic at the end offices, (2) derive the engineered traffic on all LEC trunk groups, (3) reverse engineer the sizes of the AT-POP and EO-POP trunk groups (AT&T only), (4) determine whether the transmission paths for high usage trunk groups are physically diverse from the AT, (5) determine the backbone traffic distribution for each IEC. This section describes the modules in this step, and concludes with a brief discussion of the importance of appropriately representing the traffic matrices in TAMI. All the computations and algorithms used in Step 1.2 are described more thoroughly in a number of TAMI references: (7, 3).

To adapt to differences in each carrier's data and modeling assumptions, there is a dedicated module for each IEC: *attlive*, *mcilive*, *sprlive*. These modules are referred to as the "undamaged data preparation modules." Because the modules require a number of input files, a common "keyfile" concept was developed. This file contains labeled sections for each carrier, which lists all the files specific to that carrier. A general LEC section lists file names common to all three carriers. The key file is supplied to each module, which then scans the appropriate sections for the names of its input files. The keyfile format is depicted in Appendix B.

The data preparation modules compute a number of variables required at later stages. To simplify the handling of output files, these variables are incorporated into a single, multi-section output file. Each section is identified by a unique label. The exception is the backbone traffic distribution, which is stored in its own file by convention.

Engineered traffic numbers are computed in the data preparation modules at every possible point through the networks, including:

- access traffic at the end offices
- traffic engineered to be carried on the high-usage trunk group
- traffic engineered to be carried on the EO-AT trunk group
- aggregate traffic engineered to be carried from an AT to the IEC POP
- total traffic engineered to arrive at the IEC switch.

In addition, the backbone traffic distribution is computed to determine the proportion of traffic arriving at an IEC switch that gets distributed to each destination IEC switch.

Specific to *attlive*, sizes of EO-POP and AT-POP trunk groups are calculated. Unlike MCI and Sprint data, AT&T data does not indicate the sizes of these trunk groups connecting the LEC networks to its toll network. Trunk group sizes are engineered using the engineered traffic and telco standard grade of services targets.

Because physical transmission paths are not provided in the LEC networks, a physical diversity model is applied to all high usage trunk groups. This model determines whether the high usage trunk groups are likely to follow a physical path through the site of the local access tandem, or through a route that is diverse from the access tandem. This results determines whether high usage trunk groups are knocked out when there is damage to the local access tandem facility.

TAMI Traffic Matrices

The backbone traffic distribution is of particular importance in this stage. To illustrate this, it is necessary to explain how TAMI stores its "traffic matrix." In the abstract, the traffic matrix describes how much traffic is offered from EO i to EO j through IEC c :

$$T_{ij,c}$$

However, deriving this structure requires a large amount of computing time, and storing it provides an even greater barrier. Given approximately 15,000 end offices, $T_{ij,c}$ would require 675 million double precision floating point numbers, or about 5.4 gigabytes of disk storage. TAMI addresses this issue by aggregating traffic where possible, only distributing it at network branching points. Consider $ACK_{k,c}$, which is the total traffic offered by EO k to IEC c . This variable requires the storage of only $k \times c$ values. $ACK_{k,c}$ will travel through the LEC network until it arrives

at an IEC switch. At this point, it must be distributed from switch $S_{i,c}$ in IEC c to all the other switches in the backbone ($S_{j,c}$), using a distribution matrix:

$$S_{ij,c}$$

Because there are many fewer long distance toll switches than there are end offices, $S_{ij,c}$ is a relatively small structure that can be computed and used to distribute traffic through the toll networks. Traffic terminating at a switch, $S_{j,c}$, is the aggregate of traffic from all source switches, and must be distributed to the destination end offices to complete. Here, it is assumed that traffic terminates to end offices in the same proportions by which it originates. Understanding these traffic matrix calculations is essential for understanding many of the computations and variables required in Step 1.2 and in subsequent steps. The traffic matrix computations are presented in more detail in Reference 7 (Network Congestion Analysis).

The undamaged data preparation modules compute the access traffic ($ACK_{i,c}$) for each EO, and the backbone traffic distribution matrix, $SS_{ij,c}$. Together, these are used to describe the "end-to-end traffic matrix," $T_{ij,c}$, required by TAMI.

2.2 (Step 3) Monte Carlo Sampling Loop

The purpose of this step is to run steps 4 through 6 for a single damage vector at a time, sampling as many damage vectors as required for results to converge. The Monte Carlo sampling process is described in more detail in Reference 7.

This step consists of a single software module, `tami`. Because `tami` controls steps 4 through 6, it is often referred to as the "controlling logic" for the TAMI model. `Tami` supports all of the command-line options of the modules it controls, which are passed down to these modules when they are called. In addition, `tami` reads and interprets the keyfile, and passes file names from it to called modules.

The main purpose of `tami` is to control the damage vector sampling process. It begins by running steps 4 through 6 on the first damage vector in the damage files. For the data flow depicted in Exhibits 2-2 and 2-3, it invokes all modules in the appropriate order, builds any necessary input files for each module, and passes appropriate command line arguments to each module. It then uses the error output by `keepstats` to decide if it needs to run steps 4 through 6 again using the next damage vector. The damage vector sampling loop continues until convergence is reached.

This step also coordinates multiple damage vector bins, as defined in the `tami` keyfile, if multiple damage scenarios are included in the same damage files. A set of cumulative results files are maintained for each bin. As `tami` runs, it prints ongoing status to the screen, such as the bin and damage vector currently being sampled, the module currently being run, and start and end time stamps for each loop.

2.3 (Step 4.1) Pre-Process Damaged IEC Networks

The goal of this step is to derive QTCM input files for each IEC, incorporating damage from the current sampled damage vector. In addition, for MCI, additional steps are performed to test backbone connectivity under the current damage vector.

Step 4.1 consists of three modules: `qtrans`, `mkrouit` (MCI only) and `qmod_mci` (MCI only). `Qtrans` translates the `qlink` and `switch` files into QTCM file format. Because MCI uses hierarchical routing, `mkrouit` is also required in order to derive a point-to-point routing table, which is incorporated into the QTCM file format.

Finally, `qmod_mci` is run on the MCI QTCM file using a very small offered load as a "trickle current." The resulting output blockage matrix, `ppmeanfile.mci`, will indicate whether at least one undamaged direct or indirect route exists between each switch pair through the hierarchical backbone. This information is required by the `mciwdmg` module to determine connectivity through the IEC.

2.4 (Step 4.2) Pre-Process Damaged LEC Networks and Traffic Matrix

This goal of this step is to incorporate the current damage vector into the LEC networks (EO to IEC switch) and traffic matrix offered to the PSN. This step uses the engineered (undamaged) network and traffic descriptions computed in step 1.2 as a baseline for applying damage. The output from this step is an input to the lecam module in Step 5.1.

Step 4.2 consists of four modules: attwdmg, mciwdmg, sprwdmg, and merge. Each of the "wdmg" modules handles the specific details of applying damage to the network and calculating the traffic matrix. These modules results in output network files for each IEC. Merge combines the sections of these files that are common to all three carriers. It also engineers portions of the LEC which require knowing the combined traffic from all IECs.

2.5 (Step 5.1) Perform LEC Blockage Calculations

There purpose of this step is to perform the blockage calculations in the LEC networks. Combined with the IEC blockages from Step 5.2, this step calculates overall PSN blockage statistics for the current sampled damage vector.

This step consists of a single module, lecam. The primary functions of lecam are as follows:

- (1) calculate LEC blockages
- (2) pass traffic up to IECs (QTCM) for IEC blockage calculations
- (3) examine all (LEC and IEC) blockage calculations to determine convergence
- (4) upon convergence, use EO pair file to calculate end-to-end blockage through each IEC
- (5) separately calculate NS/EP blockages, dependent on NS/EP options (e.g., LEC TCR, E-RTNR, etc.)
- (6) write these results to an output file

The output from lecam is used by the keepstats module in Step 6.

2.6 (Step 5.2) Perform IEC Blockage Calculations

The purpose of this step is to calculate the blockage through each IEC based on traffic offered from Step 5.1. The execution of this step is used as a subroutine to Step 5.1, which controls its execution.

This step consists of the QTCM model. Separate versions (qmod_att, qmod_mci, qmod_spr) have been created for each IEC since input and output filenames are hardcoded for each carrier. The purpose of QTCM is to calculate the point-to-point blockages in each IEC backbone network. These results are written to the 'ppmeanfile' output files which are interpreted by Step 5.1.

2.7 (Step 6) Post-Process Analysis Results

The purpose of this step is to maintain cumulative statistics for the Monte Carlo sampling process. Each time PSN performance results are determined for a given damage vector, this step accumulates them into the running averages and totals and calculates the "error" in the sampling process.

Step 6 consists of a single module, keepstats. The error calculated by keepstats is used by the controlling logic in Step 3 to determine if another damage vector should be sampled or if results have converged.

3.0 MODULE DESCRIPTIONS

3.1 attlive: Build AT&T Live Network and Traffic

Purpose The purpose of this module is to complete the representation of the undamaged AT&T network. This module uses existing publicly available data on that network along with telco engineering and reverse engineering methods to completely represent the AT&T network from the TGs down to the LECs, and to build a traffic matrix to populate that network. This module is used in conjunction with attwdmg which introduces damage effects into the network data files. The final output of the two step process after the attwdmg module is input into the LECAM module.

Call Syntax attlive -k <key file> [options]

options:	special syntax:	function:
-k	<keyfile>	reads in input file <key file>
-o	<outfile>	reads in output file name. If not specified, default file name is att2lecam.step1
-t	<#>	switch index for backbone test, (-1) for all switches
-h		invokes new High Usage occupancy and overflow algorithm commands (this setting is now considered the default setting)
-?		user help--prints call syntax and exits without running

example attlive -k dplive.key -h (spaces optional)

**Input
Files**

key file This file contains hardcoded instructions for opening up and reading in the various data files to be used in this module.

format SEE SECTION 2.1/EXHIBIT 2-3

**Output
Files**

att2lecam file This file contains the formatted output data to be used in the LECAM module. It contains a header section followed by 17 data sections.

Includes	"attlive.h"	Defines global network and traffic variables and constants.
	"lecam.h"	Defines network sizing constants.
	"fileio.c"	User-defined I/O functions; see Appendix A.
Constants	Constants used in attlive and defined in "attlive.h":	
	OVFLW	0.90 AT&T overflows 10% from HU to final
	TRKOCC	0.95 HUs are 95% occupied
	INTRA	0.0 multiplier for inter-switch traffic to add intra-switch traffic
	Constants used in attlive and defined in "lecam.h":	
	MAX_AT	1000 maximum number of access tandems
	MAX_EO	19250 maximum number of end offices
	MAX_POP	575 maximum number of points of presence
	MAX_SWITCH	130 maximum number of switches
Global Variables		
	global variables defined in "attlive.h"	
integer	KEYTOG	toggle to indicate input 'file name' was read in successfully
	NUMEO	number of end offices
	NUMAT	number of access tandems
	NUMPOP	number of points of presence
	NUMSW	number of switches
	ATPOPSIZE	the number of trunks between the AT and the POP
	HAP[MAX_AT][ATPOPMAX]	number of high usage trunks between the AT and the POP
	AT[MAX_EO]	traffic at the AT
	ATPOP[MAX_EO]	traffic between the AT and the POP
	HUPOP[MAX_EO]	traffic between the high usage AT and the POP
	TYPE[MAX_EO]	type of homing between the AT and the SW
	SW[MAX_EO]	traffic at the switch
	LATA[MAX_EO]	traffic at the LATA
	COC[MAX_EO]	central office code homings
	IMT[MAX_SWITCH][MAX_SWITCH]	matrix of backbone trunk traffic
	SEP[MAX_EO]	size of trunks between EO and POP
	SAP[MAX_AT][ATPOPMAX]	size of trunks between AT and POP
	COCSW[MAX_SWITCH]	matrix of homings between switches and COCs
	PhysDiv[MAX_EO]	physical diversity value for each EO of TYPE = 3
	SW_nlata[MAX_SWITCH]	number of LATAs that a switch serves
	popswitch[MAX_POP]	POP switch homing
	D3DONE[MAX_AT][ATPOPMAX]	a logical control variable to avoid double counting AT to POP trunk groups
	TOT_IMT	total number of backbone trunks at the switch
	EOLOC[MAX_EO][2]	location of each EO
	ATLOC[MAX_AT][2]	location of each AT
	SWLOC[MAX_SWITCH][2]	location of each SW
	POPLOC[MAX_POP][2]	location of each POP
real	IMTTraf[MAX_SWITCH][MAX_SWITCH]	traffic between switches

	TEP[MAX_EO]	traffic EO to POP
	TEA[MAX_EO]	traffic EO to AT
	TAP[MAX_AT] [ATPOPMAX]	traffic EO to POP
	ACSlec[MAX_SWITCH]	LEC access capacity at the switch. This is the sum of the D3[POP] s for POPs homed to SW. This is a function of TEP and TAP. Alternatively, ACSlec is the sum of AC[k] for all EOs homed to SW. This is computed before damage.
	ACSiec[MAX_SWITCH]	IEC access capacity at the switch. ACSiec is used to compute ACSPOP. ACSiec is a function of IMTTraf.
	D3[MAX_POP]	AC[MAX_EO] total access capacity access traffic engineered from LEC switches to POP. This is the access traffic arriving at POP from the EO-POP and AT-POP TGs homed to it. D3 is a function of TEP and TAP. This is equal to intraswitch plus interswitch traffic at a POP
	ACPiec[MAX_POP]	access traffic engineered from IEC switches to POP
	PropIntra[MAX_SWITCH]	proportion of intraswitch traffic
	fProp[MAX_SWITCH]	ratio intraswitch traffic to interswitch traffic
	Overflow[MAX_EO]	traffic overflowing AT to POP on high usage trunks
character	swclli[MAX_SWITCH] [12]	matrix of cli codes for each switch
	global variables defined in "keyfiles.h"	
FILE	*fileptr	points to an open input file
	*outfile	points to an open output file
character	eo_file[80]	name of the EO file
	at_file[80]	name of the AT file
	iec_eo_file[80]	name of the IEC EO file
	iec_at_file[80]	name of the IEC AT file
	iec_sw_file[80]	name of the IEC SW file
	iec_pop_file[80]	name of the IEC POP file
Local		
Variables	Variables local to main()	
extern	character	*optarg
	integer	optind
	a string containing a single command line argument.	
	the number of single command line arguments to be processed, supplied externally by the operating system	
character	c	a command line option character
	outfile[80]	the name of the output file
	line[200]	buffer for parsing a single input line from a file
	livekeyfile[80]	the name of the input key file for the live networks
	**argv[]	an array containing all of the command line arguments
integer	err=0	error flag indicating a problem with the command line arguments
	otog=0	indicates use of the [-o] option (a user supplied output file name)

	ttog=0	command line parameter setting indicates the use of the [-t] option (currently not used)
	htog=0	indicates the [-h] option (use of new high usage rules, this is now the default setting)
	SWA	the index of a switch for printing of debug statements in TrafDist()
	test	not used
	AC_tot=0	sums the total access capacity across all EOs
	t3_num=0	the number of end offices that overflow from HU to final homing
	ovflw_count=0	the number of end offices that overflow from HU to final homing (same as t3_num)
	Dummy	used to read in a dummy integer value
	i, j, k, l, m, n, pm	loop count variables
	SEP_total=0	sums the number of high usage trunks between EOs and POPs
	argc	the number of command line arguments
	real ovflw_total=0	the total amount of traffic which overflows from the high usage trunks
	TEP_total=0	the total amount of traffic between EOs and POPs
	TEA_total=0	the total amount of traffic between EOs and ATs
	wovflw_total=0	the weighted overflow based on access capacity across all EOs
	wovflw_denom=0	the total access capacity across all EOs

integer	PoissonN(Ain, Bin) phdiv(eo, at, pop)	traffic calculator for engineering number of trunks determines physical diversity based on collocation

Function Tree

Algorithmic Description

This module completes the representation of the AT&T network and the traffic that is carried on that network. The procedure is to distribute the AT&T traffic down through the LECs then reverse engineer the sizes of the TGs needed to carry this traffic in order to build a reasonable model of the network and its relationship to the LECs. A similar process will be undertaken with MCI and Sprint.

The `main()` routine contains most of the algorithmic code for this module. After the command line toggles have been interpreted, the `main()` routine begins by passing the `<keyfile>` argument into `LoadKeyfile()`, which reads in the names of the LEC and IEC (AT&T) files. It then calls `Init()`, which initializes all network variables. `Readfile()` is called next to read in all network data. `Main()` then opens the `<outfile>` and proceeds to perform the core of the algorithmic work in this module, in the following order:

- 1) Call `PoissonAmod()` which uses the number of backbone/IEC trunks connecting switch A to switch B (and B to A) to compute the traffic across the trunks from A to B (and B to A).
- 2) Count the total number of central office codes associated with the end office homed to each switch.
- 3) Engineer total access traffic (two-way) between the LEC and the switch and engineer total access traffic (two-way) between the switch and the IMTs by summing traffic from all backbone trunks that end at a switch. (These two values are equal if `fprop` is disabled, i.e. set equal to 1.)
Keep a running total of the number of IMTs and total traffic carried by them.
- 4) Compute the average access capacity of each end office by multiplying the total traffic at each switch by the ratio: *number of EO COCs/total number of COCs*;

Keep a running total of the overall access capacity.

- 5) Engineer three types of LEC trunk group size homings and the traffic carried on them;
Sum EO-AT traffic up to AT-POP traffic; and
Keep diagnostics.

Type 1. HU-only homing.

Engineer the size of the trunk groups that send traffic from the end office to the switch.

Call `PoissonNmod()` to engineer the size of the trunk groups.

Set `traffic = access capacity`

Type 2. AT-only homing.

Engineer the traffic sent from the end office to the Access Tandem and then to the switch.

Calculate EO-AT traffic.

Sum EO-AT traffic up to AT-POP traffic.

Type 3. HU with AT overflow.

Engineer the size of the trunk groups that use a combination of **Type 1** and **Type 2**

Call `PoissonNmod()` to engineer the number of trunks needed to send communications directly to the switch.

Call `ErlangB()` to engineer overflow capacity sent first through the AT and then to the switch.

Calculate traffic EO-AT as $AC * (\text{Overflow traffic})$.

Calculate traffic EO-POP as $AC * (1 - \text{Overflow traffic})$.

Sum traffic EO-AT up to traffic AT-POP.

- 6) Reduce access capacity by 1/2 to capture access capacity only, assuming access = egress at an EO. Perform this for each EO in the LEC and for each switch in the IEC.
- 7) Use AT-POP Traffic and `PoissonNmod()` to calculate the number of AT-POP trunks.
- 8) For each Type 3 homing (HU with AT overflow), call `phdiv()` determine physical diversity. (i.e. collocated = not physically diverse; not collocated = physically diverse). This is necessary to determine if physical damage to an AT site will also cause damage to the HU homing.
- 9) Calculate AT traffic engineered between LEC switches and POP.
Sum HU traffic up to POPs.
Sum AT traffic up to POPs
- 10) Calculate the amount of interswitch access traffic at a POP.
Determine intraswitch traffic.
- 11) Calculate the proportion of intraswitch traffic
- 12) Calculate one-half the value of: traffic EO to POP and traffic EO to AT.

At this point the calculation of Traffic and the determination of Trunks is complete in the LEC

- 13) Check for EOs with $AC = 0$. Print warning if found.

- 14) If `ttog` set 'on' then call `TrafDist()`. This optional routine is not part of TAMI but was used to perform testing of best modeling assumptions. This routine attempts to define the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
- 15) Call `OutWrite()` which formats and writes all variables to the outfile which is a LECAM input file.

ATPOPSIZE	the number of trunks between the AT and the POP

**Algorithmic
Description**

This function reads in the live network variables from several input files. The input is performed in the following sequence:

- 1) Read in LEC data from IEC EO file which contains homing chains from EO-SW and count number of EOs
- 2) Read in LEC data from the IEC AT (HAP) file which describes AT-POP homings, which may be multiple.
- 3) Read in EO V-H coordinates from the EO file.
- 4) Read in AT V-H coordinates from the AT file.
- 5) Read in Switch V-H coordinates from the IEC switch file. Also read in and store the CLLI code and the number of LATAs that a switch serves
- 6) Read in POP V-H coordinates from the IEC POP file. Also read in POP switch homing.
- 7) Read the undamaged IMT matrix from qlink. This is the undamaged matrix of IMT capacity. Divide each one-way TG into 50% i->j and 50% j->i to account for bi-directional traffic.

Inputs

integer SWA the index of a switch for printing of debug statements

Outputs

returns none

Purpose This optional routine is not part of TAMI but was used to perform testing of best modeling assumptions.

Called By main ()

Calls To none

Local Variables

integer i, j loop count variable

real vdiff vertical difference
 hdiff horizontal difference
 dist distance between switches of interest
 weight a weighting factor
 Sum[] sum of access traffic of all switches

Global Variables

character swclli[][] matrix of cli codes for each switch

integer NUMSW=0 number of switches

real IMTTraf[][] traffic between switches
 ACSiec[] IEC access capacity at the switch
 SWLOC[][] location of each SW

Algorithmic Description

This routine defines the community of interest weighting that describes how much or little traffic a switch will send another due to their proximity. The approach is to assume that equidistant switches would send each other traffic proportional to the ACSiec of both the source and destination switches:

$$t[i][j] = ACSiec[i] * ACSiec[j] / (SUM(k=1..NUMSW; k!=i) ACSiec[k])$$

This quantity ignores community of interest, so it can be modified as follows:

$$t[i][j] = ACSiec[i] * (ACSiec[j] * func(distance)) / (SUM(k=1..NUMSW; k!=i) \{ACSiec[k] * func(distance)\})$$

The func(distance) can be any type of weighting function. Here it is assumed that it will be some function inversely proportional to the distance between the two switches. For the purposes of this routine, func(distance) is estimated as follows:

$$t[i][j] = ACSiec[i] * (ACSiec[j] * func(distance)) / \\ (SUM(k=1..NUMSW; k!=i) \{ACSiec[k]\})$$

where the sum in the denominator is not weighted. Therefore, the weight is approximated by:

$$func(distance) = (SUM(k=1..NUMSW; k!=i) \{ACSiec[k]\} * t[i][j]) / ACSiec[i] * ACSiec[j]$$

Note: IMTTraf[i] [j] is equal to t[i][j] in the code.

After declaring local variables and initializing values, the function proceeds to execute the following steps:

- 1) Compute sum of the access traffic for all unique switches
- 2) Compute results for all switch pairs
- 3) Calculate distance from switch A to all others
Calculate estimate of weight
Print selected results
- 4) Compute results for switch pairs from switch A to all other switches, printing all the results
- 5) Calculate distance from switch A to all others
Calculate estimate of weight
Print all results.

Inputs	none	
Outputs	please see description of output file "att2lecam file" under the module description section.	
Purpose	to format and print data for input to lecam.c	
Called By	main()	
Calls To	none	
Local Variables		
integer	count, k, l, m, n	loop count variables
Global Variables		
integer	NUMEO	number of end offices
	NUMAT	number of access tandems
	NUMPOP	number of points of presence
	NUMSW	number of switches
Algorithmic Description	This function writes out all output variables to the output file "att2lecam.step1" for a list of these variables and the file format see the description of the output file under the module description section.	

3.2 mcilive: Build MCI Live Network and Traffic

Purpose The purpose of this module is to complete the representation of the undamaged MCI network. This module uses existing publicly available data on that network along with telco engineering and reverse engineering methods to completely represent the MCI network from the TGs down to the LECS.

This program also allocates traffic from the switches down to the EOs, creating traffic patterns along the way on EO-POP, AT-POP, and EO-AT TGs and builds a traffic matrix. This module is used in conjunction with mciwdmg which introduces damage effects into the network data files. The final output of the two step process after the mciwdmg module is input into the LECAM module.

Call Syntax `mcilive -k <key file> [mandatories][options]`

<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
-k	<keyfile>	reads in input file <key file>
<i>optional:</i>	<i>special syntax:</i>	<i>function:</i>
-o	<outfile>	reads in output file name. If not specified, default file name is mci2lecam.step1
-t	<#>	invokes Trafdist(), traffic distribution matrix routine, default setting
-h		invokes new High Usage occupancy and overflow algorithm commands (this setting is now considered the default setting)
-p		High Usage overflow default setting override
-?		user help—prints call syntax and exits w. without running

example `mcilive -k dplive.key -h (spaces optional)`

Input Files

key file	This file contains hardcoded instructions for opening up and reading in the various data files to be used in this module.
format	SEE SECTION 2.1/EXHIBIT 2-3

Output Files

mci2lecam file	This file contains the formatted output data to be used in the LECAM module
format header:	<p>* MCI live data file (damage added in MC loop)</p> <p><IEC label> ("IECid=", c3) <switch size> ("SWITCH_SIZE", i3) <POP size> ("POP_SIZE", i3) <AT size> ("AT_SIZE", i4) <EO size> ("EO_SIZE", i5) <AT to POP size> ("ATPOPSIZE", i3)</p>

Includes	"mcilive.h"	Defines global network and traffic variables and constants
	"lecam.h"	Defines network sizing constants
	"fileio.c"	User-defined I/O functions; see Appendix A

Constants Constants used in mcilive and defined in "mcilive.h":

OVFLW	0.25	MCI overflows 75% from HU to final
TRKOCC	0.95	HUs are 95% occupied
NODIRECT_WEIGHT	0.3	indicates no direct weight value
MAX_ITER	100	maximum number of iterations for traffic algorithm
TOLERANCE	0.1	precision level

Constants used in mcilive and defined in "lecam.h":

TRUE	1	true
FALSE	0	false
MAX_AT	1000	maximum number of access tandems
MAX_EO	19250	maximum number of end offices
ATPOPMAX	9	maximum number of POPs a single AT may home to
MAX_POP	575	maximum number of points of presence
MAX_SWITCH	130	maximum number of switches
MAX_LATA	1000	maximum number of LATAs
MAX_REGION	5	maximum number of regions covered by a LATA

Global Variables global variables defined in "mcilive.h"

integer	KEYTOG	toggle to indicate input 'file name' was read in successfully
	GSEP	given size of EO to POP connection
	GSAP	given size of AT to POP connection
	NUMEO	number of end offices
	NUMAT	number of access tandems
	NUMPOP	number of points of presence
	NUMSW	number of switches
	ATPOPSIZE	the number of trunks between the AT and the POP
	HAP[MAX_AT][ATPOPMAX]	number of high usage trunks between the AT and the POP
	AT[MAX_EO]	traffic at the AT
	ATPOP[MAX_EO]	traffic between the AT and the POP
	HUPOP[MAX_EO]	traffic between the high usage AT and the POP
	TYPE[MAX_EO]	type of homing between the AT and the SW
	SW[MAX_EO]	traffic at the switch
	LATA[MAX_EO]	traffic at the LATA
	COC[MAX_EO]	central office code homings
	IMT[MAX_SWITCH][MAX_SWITCH]	matrix of backbone trunk traffic
	SEP[MAX_EO]	size of trunks between EO and POP
	SAP[MAX_AT][ATPOPMAX]	size of trunks between AT and POP
	COCSW[MAX_SWITCH]	matrix of homings between switches and COCs
	PhysDiv[MAX_EO]	physical diversity value for each EO of TYPE = 3
	SW_nlata[MAX_SWITCH]	number of LATAs that a switch serves
	popswitch[MAX_POP]	POP switch homing
	D3DONE[MAX_AT][ATPOPMAX]	a logical control variable to avoid double counting AT to POP trunks groups

	TOT_IMT	total number of backbone trunks at the switch
	EOLOC[MAX_EO][2]	location of each EO
	ATLOC[MAX_AT][2]	location of each AT
	SWLOC[MAX_SWITCH][2]	location of each SW
	POPLOC[MAX_POP][2]	location of each POP
	TAP_flag[MAX_AT][ATPOPMAX]	traffic indicator, AT to POP
real	IMTTraf[MAX_SWITCH][MAX_SWITCH]	traffic between switches
	TEP[MAX_EO]	traffic EO to POP
	TEA[MAX_EO]	traffic EO to AT
	TAP[MAX_AT][ATPOPMAX]	traffic EO to POP
	ACSlec[MAX_SWITCH]	LEC access capacity at the switch ACS[SW] derived by summing the P.01 engineered traffic on IMTs going into SW, times 0.5 for one-way. This parameter is later decremented in the allocation algorithm, and is thus unsuitable for the calculations that follow that algorithm. ACS is a function of IMTTraf.
	ACSiec[MAX_SWITCH]	exact copy of ACS[SW], but is not decremented in the allocation algorithm. ACSiec is used to compute ACSPOP. ACSiec is a function of IMTTraf.
	AC[MAX_EO]	total access capacity
	D3[MAX_POP]	access traffic arriving at POP from the EO-POP and AT-POP TGs homed to it. D3 is a function of TEP and TAP. This is equal to intraswitch plus interswitch traffic at a POP
	ACSPop[POP]	access traffic that POP can offer to SW for transmission across IMTs. This is $D3 * (ACSiec/ACSlec)$, and is written to outfile as the "real" D3, since it more accurately reflects engineered load at a pop. ACSPop is a function of IMTTraf. It is computed before D3 is decremented for damage, so that it reflects true all-alive engineered traffic. Is equal to inter switch traffic (only) at a POP.
	ACSlec[SW]	sum of the D3[POP] s for POPs homed to SW. This is a function of TEP and TAP. Alternatively, ACSlec is the sum of AC[k] for all EOs k homed to SW. This is computed before damage.
	ACPied[MAX_POP]	access traffic engineered from IEC switches to POP
	PropIntra[MAX_SWITCH]	proportion of intraswitch traffic
	fProp[MAX_SWITCH]	ratio intraswitch traffic to interswitch traffic
	Overflow[MAX_EO]	traffic overflowing AT to POP on high usage trunks
	TAPA[MAX_AT][ATPOPMAX]	traffic AT to POP
	TAP_target[MAX_AT][ATPOPMAX]	target amount of traffic AT to POP
double	FO[MAX_EO][2]	divided into HU traffic (0) and FINAL traffic (1)
character	swclli[MAX_SWITCH][12]	matrix of clli codes for each switch
	clli[12]	individual clli code
	equip[4]	four character equipment code

global variables defined in "keyfiles.h"

structure	AT_hmg[MAX_AT] <i>with fields:</i>	of type AT_hmg_struct
integer	type2 type3	number of Type 2 homing switches number of Type 3 homing switches
real	ovflw_total TEP_total TEA_total	the total amount of traffic which overflows from the high usage trunks the total amount of traffic between EOs and POPs the total amount of traffic between EOs and ATs

wovflw_total	the weighted overflow based on access capacity across all EOs
wovflw_denom	the total access capacity across all EOs
sum2_AC=0	sum of the access capacity for Type 2 switches
sum3_AC=0	sum of the access capacity for Type 3 switches

Component Functions

void	Init()	initializes all network variables
	ReadFiles()	reads in each section of the input files specified in the <keyfile>
	Trafdist()	This routine defines the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
	OutWrite()	writes out each section of the output file defined in "mcilive.h"
void	LoadKeyfile()	loads input file names from the <keyfile> specified in the command line
double	ErlangB()	traffic calculator for engineering overflow capacity using ErlangB blocking
	PoissonA()	traffic calculator for engineering traffic from switchA to switchB and vice-versa
	PoissonAmod()	traffic calculator for engineering traffic from switchA to switchB and vice-versa
integer	phdiv()	determines physical diversity based on collocation

Function Tree

Algorithmic Description

This module completes the representation of the MCI network and the traffic that is carried on that network. The procedure is to distribute the MCI traffic down through the local exchange carriers (LEC) in order to build a reasonable model of the network and its relationship to the LECs. A similar process is undertaken with AT&T and Sprint.

MCI provides the sizes of High Usage trunks (HU) and access tandems (AT) to point-of-presence (POP) trunk groups (TG), which are used to engineer traffic in the LECs. Where homings through an AT are involved, traffic must be allocated down from the AT to the end offices (EO). There are several ways to do this, each with drawbacks and advantages. This module uses the most accurate method where possible; cases where this method breaks down are detected, and a secondary method is used to allocate traffic from these ATs down to their EOs.

The `main()` routine contains the majority of the algorithmic code for this module. After the command line toggles have been interpreted, the `main()` routine begins by passing the `<keyfile>` argument into `LoadKeyfile()`, which reads in the names of the LEC and interexchange (IEC) files. It then calls `Init()`, which initializes all network variables. `Readfile()` is called next to read in all network data. `Main()` then opens the `<outfile>` and proceeds to perform the core of the algorithmic work in this module, in the following order:

- 1) Call `PoissonAmod()` which uses the number of backbone/IEC trunks to compute the backbone traffic across the trunks.
- 2) Count the total number of central office codes associated with the end office homed to each switch.
- 3) Engineer total interswitch traffic at each switch by summing traffic from all backbone trunks that end at a switch. (Since MCI trunks are not bi-directional, must add access and egress backbone traffic at a switch.)
Set access traffic = to one half of total traffic.
- 4) Use a **3-Pass** algorithm to allocate traffic to individual LEC network segments, for 3 types of LEC trunk group size homings: **Type 1**, HU-only homings, **Type 2**, AT-only homings, and **Type 3**, homings that involve an HU overflowing to the AT (final) homing :

In general calculate:

- AC (access traffic offered by an EO)
- TEA (traffic going on the EO-AT TG, if any)
- TAP (traffic going on the AT-POP TG, if any)
- TEP (traffic going on the EO-POP TG, if any).

PASS 1 Engineer the straightforward cases and set up statistics to support the more complex cases.

Type 1. HU-only homing.

Call `PoissonAmod()` to engineer AC directly from the EO-POP TG size, assuming P.01, (1% blocking).
Set EO-POP traffic equal to AC.
De-allocate EO AC from switch (SW) traffic.

Type 2. AT-only homing.

Traffic over AT-only homings cannot be allocated until the effect of overflow from HU trunks is determined. In the first pass we sum up central office codes (COC) for all EOs homed to the same AT-POP TG.

Type 3. HU with AT overflow.

Traffic for HU homings that overflow through the AT is calculated using the methodology shown below. In later passes, it is determined if this method broke down for a particular AT. If so, an alternative algorithm is used.
The preferred algorithm is:

- A) Call `PoissonAmod()` to engineer communications sent directly EO-POP (with P.80 blocking on the HU TG meaning the last trunk in the TG is occupied 80% of the time).
- B) Call `ErlangB()` to engineer overflow capacity sent first through the AT then to the SW. Traffic overflowing to the AT is computed by offering AC to the HU TG using Erlang B blocking. This Erlang B blockage is used to determine traffic carried on the HU, and traffic that must overflow from the EO to the AT.
- C) Compute the running sum of EO-AT traffic for each AT-POP TG to determine if our methodology would create more AT-POP traffic than could be handled by the AT-POP TG. As a precautionary measure, compute the variables required by the backup algorithm: the sum of COCs and overflow-weighted COCs to each AT-POP TG for the **Type 3** homings.

PASS 1.5 This pass only applies to **Type 3** EOs,
No network variables are calculated. Only determines if first-choice numbers in previous pass are valid.

Type 1. HU-only homing. No calculations for this pass.

Type 2. AT-only homing. No calculations for this pass.

Type 3. HU with AT overflow.
Determines whether the first or second-choice algorithm will be used for allocating AT-POP traffic down to EOs. If the first-choice algorithm won't work (i.e. causes AT-POP traffic to be greater than what the AT-POP TG can accommodate), then a flag is set for the next pass, and the **Type 3** overflow-weighted COCs are combined with the **Type 2** COCs to create the total needed by the alternative algorithm.
If the first choice algorithm will work, then the share of AT-POP traffic already allocated to **Type 3** EOs is subtracted from the amount available to be allocated to the **Type 2** EOs that use the same AT.

PASS 2 The second pass allocates traffic to the **Type 2** EOs (AT-only homings) regardless of the method used for **Type 3** traffic allocation. Calculate traffic the **Type 3** EOs for the cases where the alternative allocation algorithm must be used.

Type 1. HU-only homing. No calculations for this pass.

Type 2. AT-only homing.
Use COCs and the AT-POP traffic to engineer the access capacity and the EO-AT traffic and then to the SW.
Calculate AC based on COCs
Allocate traffic AT-POP
Calculate traffic EO-AT
De-allocate AC traffic at the SW

Type 3. HU with AT overflow.
Use second-choice algorithm:

If hto is set to true

Allocate AT-POP traffic based on overflow weighted COCs
Replace previous values of TEA and AC
De-allocate AC traffic at the SW

else

Allocate AT-POP traffic based on HU overflow weighted COCs

De-allocate AC traffic at the SW
Replace previous values of EO-AT traffic and AC.

At this point all LEC network traffic variables have been engineered and the calculation of Traffic and the determination of Trunks is complete in the LEC .

- 5) Reduce AC by 1/2 to capture access capacity only, assuming access = egress at an EO. Perform this for each EO in the LEC and for each SW in the IEC.
Sum traffic from LECs up to SW (ACS1ec).
- 6) For each **Type 3** homing (HU with AT overflow), call `phdiv()` to determine physical diversity. (i.e. collocated = not physically diverse; not collocated = physically diverse). This is necessary to determine if physical damage to an AT site will also cause damage to the HU homing.
- 7) Compute and print overflow and occupancy summary statistics:
Sum AC for each **Type 2**.
Sum **Type 2** homings.
Verify actual engineered overflow from the HU TG to the POP.
Sum AC for each **Type 3**.
Calculate average and weighted average overflow.
Calculate EO-POP and EO-AT traffic.
- 8) Use ACS1ec and results of `phdiv()` to recalculate SW AC. Backbone trunks that connect to a SW with no EO homings should not be included in calculating SW AC. This occurs when a SW is collocated.
- 9) Calculate AT traffic engineered between LEC switches and POP.
Sum HU traffic up to POPs.
Sum AT traffic up to POPs

Switch and POP variables are now calculated, including versions that include interswitch traffic only, and versions that include both inter and intraswitch traffic. From this, the proportion of intraswitch traffic at each switch (PropIntra) is calculated.

- 10) Calculate the amount of interswitch access traffic at a POP.
Determine intraswitch traffic.
- 11) Calculate the proportion of intraswitch traffic
- 12) Calculate one-half the value of : traffic EO to POP and traffic EO to AT.

At this point the calculation of Traffic and the determination of Trunks is completed in the LEC

- 13) If `ttog` set true then call `TrafDist()`. This routine defines the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
- 14) Call `OutWrite()` which formats and writes all variable to the outfile which is a LECAM input file.

Inputs none; operates on global variables

Outputs

global	integer	NUMEO=0	number of end offices

ATPOPSIZE

the number of trunks between the AT and the POP

**Algorithmic
Description**

This function reads in the live network variables from several input files. The input is performed in the following sequence:

- 1) Read in LEC data from the IEC EO file which contains homing chains from EO-SW and count number of EOs.
- 2) Read in LEC data from the IEC AT (HAP) file which describes AT-POP homings, which may be multiple.
- 3) Read in EO V-H coordinates from the EO file.
- 4) Read in AT V-H coordinates from the AT file.
- 5) Read in POP V-H coordinates from the IEC POP file. Also read in POP switch homing.
- 6) Read in Switch V-H coordinates from the IEC Switch file. Also read in and store the CLLI code and the number of LATAs that a switch serves
- 7) Read the undamaged IMT matrix from `qlink`. This is the undamaged matrix of IMT capacity. Divide each one-way TG into 50% $i \rightarrow j$ and 50% $j \rightarrow i$ to account for bi-directional traffic.

Inputs	none	
Outputs		
returns	none	
Purpose	Before writing network variables to the final output file, we perform the final major task of MCILIVE: creation of the backbone traffic distribution. This matrix helps us know how to handle traffic once it travels up from the LEC networks to the IEC toll switch. Specifically, it determines, for a given switch 'i', what proportion of its access traffic goes to each other remote backbone switch 'j'.

	<code>ACSiec[]</code>	IEC access capacity at the switch
	<code>SWLOC[][]</code>	location of each SW

Algorithmic Description

The results of TrafDist go in their own output file, 'trafdist.mci'. All other network variables are written to the master output file, 'mci2lecam.step1', which has a multi-section format comprising some header information, and a section for each network variable. The format and contents of this file are described in more detail in the OUTWRITE() function description.

TrafDist creates a switch-to-switch traffic distribution file to replace the homomorphism. It outputs this file to 'trafdist.mci' in the current directory, using the same format as the homomorphism file, so that subsequent code (mciwdmg) does not have to be altered to read in a different format.

Step I

In this step, a first approximation of the Tij switch-to-switch matrix is developed. The algorithm first populates Tij pairs for which direct trunk groups exist. (Note: the only Tij pairs are those between class 3 switches and two class 1 switches that serve LEC traffic directly). The Tij pairs are populated with the P.01 engineered load, (since MCI trunks are one-way, this doesn't need to be divided by 2). The Tij entry for the class 1 switches is further divided by 3, since by inspecting the data, these two class 1 switches (i,j) need about 1/3 of their IMTs to serve their own originating traffic. Since direct trunk groups account for 75% of MCI's backbone capacity, most of the proportions are calculated this way. Traffic between the remaining 25% of the switch pairs is estimated by using the proportions of access traffic * 0.3, e.g.;

$$Tij = 0.3 * offd(i) * offd(j) / (\text{sum of } offd(k) \text{ for all } k \neq i)$$

where `offd(i)` = offered traffic of the switch

The 0.3 weighting signifies that since the switch pair was not important enough to have direct trunking, it probably shares less traffic than the average switch pair, which would have a weighting of 1. Since it is safe to assume that switch pairs without direct trunking are in the bottom 25% and probably have little community of interest, than any weighting between 0.2 and 0.5 would suffice to estimate this.

Step II:

Once the matrix is estimated, the access traffic for each switch is summed from the individual Tij elements. The goal of Part II is to normalize this `sumTij` to `offd_traf`, the offered traffic of the switch. `Offd_traf` for switch `i` is:

$$Offd_traf[i] = ACSiec[i] * (1 - PropIntra[i])$$

Since MCI's IMT trunking is much greater than its LEC access traffic, this is a significant step. An iterative approach is employed, whereby a switch whose sumTij estimate is greater than offd_traf systematically "negotiates" with all other switches who have the same problem. For example, if switch i and j both have sumTij greater than their respective offd_traf 's, they decrease their Tij/Tji pairs by the average of $(\text{offd_traf}[i] / \text{sumTij}[i])$ and $(\text{offd_traf}[j] / \text{sumTij}[j])$. Thus each switch decreases its traffic by the same amount, avoiding cases where $\text{Tij} \gg \text{Tji}$, or vice versa. This process is also done for cases where $\text{sumTij} < \text{offd_traf}$, and iterations continue until every sumTij is within 10% of its offd_traf or the max of 100 iterations is performed.

Step III:

At this point, we ensure that $\text{offd_traf} = \text{egr_traf}$ at a switch:

*Suppose switch i is sending traffic to a switch j , which is getting too much egr_traf . Then Tij is reduced to $\text{Tij} * (\text{offd_traf}[j] / \text{egr_traf}[j])$, and the excess $= \text{Tij} * (1 - \text{offd}/\text{egr})$ is redistributed to all other switches proportionally. The same holds true for switches that don't get enough egress traffic.*

Closing comments: When this algorithm converges, two things should be true:

1. **sumTij nearly equal to offd_traf for all switches**
2. **offd_traf nearly equal to egr_traf for all switches**

It may be the case that Tij 's for some pairs exceed their direct trunking by as much as two times, which is far off from the original estimate of P.01. However, the algorithm works because MCI's IMT capacity is \gg LEC access traffic to MCI, and so there is a good deal of room for these cases to overflow their traffic safely through hierarchical overflow routes without causing blockage. In fact it should be stressed that this algorithm is possible only because of this safety margin, so that a rough approximation that satisfies (1) and (2) above is all that is necessary. The other aspect that makes this algorithm work is that it starts with MCI's own backbone trunking, and only alters traffic patterns proportionately and evenly in each step. Thus, the traffic patterns suggested by the direct trunk groups should be preserved within an order of magnitude.

Presented below is a step by step description of the above algorithm. After declaring and initializing local declarations the following steps are executed.

Preparation for Step I

- 1) Open and read switch homing file. This file gives the homing for class 1 switches for each class 3 switch. A class 1 switch has a homing equal to a blank string.
- 2) Set class attribute of switch to **Type 1** or **Type 3**
- 3) Compare order of $\text{sw}[i].\text{clli}$ and $\text{swclli}[i]$, as a cross-check
- 4) Load clli index field
- 5) Analyze trunking from qlink file (IMT).
{This code was developed as a diagnostic of MCI's backbone, and is not necessary for the TrafDist algorithm that follows. It determines the proportion of MCI's backbone capacity used for directly connected class 3 switch pairs}.
- 6) Keep track of switch pairs that are not directly connected.
- 7) Print resulting summary stats

STEP I TrafDist algorithm starts here

- 1) Populate T_{ij} matrix with traffic
- 2) If **Type 1** (direct trunking exists):
Then size traffic to P.01 over trunk $IMT[i][j]$. Check for class 1 serving LEC traffic and adjust T_{ij} in this case.
- 3) If **Type 2** (i.e., no direct trunking exists):
Then compute opposite direction, as long as it doesn't have a direct trunk group either.
Report results

STEP II

- 1) Iterate until offered traffic ($offd_traf$) and $sumT_{ij}$ agree.
- 3) Use handshaking to reduce $sumT_{ij}$ towards $offd_traf$.
- 4) Look for another switch that also has a value of $sumT_{ij}$ that is to high, so that switches i and j can mutually lower traffic to each other by the same proportion.
- 5) Calculate proportion for switch i and j , and use average as proportion for mutually reducing T_{ij}/T_{ji} .
- 6) Discount old T_{ij}/T_{ji} from sums:
 $sumT_{ij}[i] -= T_{ij}[i][j].traf$
 $sumT_{ij}[j] -= T_{ij}[j][i].traf.$
- 7) Calculate new T_{ij}/T_{ji} as proportionately smaller:
 $T_{ij}[i][j].traf = min_prop * T_{ij}[i][j].traf$
 $T_{ij}[j][i].traf = min_prop * T_{ij}[j][i].traf.$
- 8) Impose minimum of 1 erlang between each pair:
if $(T_{ij}[i][j].traf < 1.0)$ $T_{ij}[i][j].traf = 1.0$
if $(T_{ij}[j][i].traf < 1.0)$ $T_{ij}[j][i].traf = 1.0.$
- 9) Add new T_{ij}/T_{ji} into sums, so that sums are kept up to date along the way:
 $sumT_{ij}[i] += T_{ij}[i][j].traf$
 $sumT_{ij}[j] += T_{ij}[j][i].traf.$
- 10) Use handshaking to increase $sumT_{ij}$ look for another switch that also has $sumT_{ij}$ to high, so that switches i and j can mutually lower traffic to each other by the same proportion.
- 11) Calculate proportion for switch i and j , and use average as proportion for mutually reducing T_{ij}/T_{ji}
 $min_prop = offd_traf[i] / sumT_{ij}[i]$
 $min_test = offd_traf[j] / sumT_{ij}[j]$
 $min_prop = (min_test + min_prop) / 2.0.$
- 12) Discount old T_{ij}/T_{ji} from sums
 $sumT_{ij}[i] -= T_{ij}[i][j].traf$
 $sumT_{ij}[j] -= T_{ij}[j][i].traf.$
- 13) Calculate new T_{ij}/T_{ji} as proportionately smaller
 $T_{ij}[i][j].traf = min_prop * T_{ij}[i][j].traf.$
 $T_{ij}[j][i].traf = min_prop * T_{ij}[j][i].traf.$

- 14) Impose minimum of 1 erlang between each pair
 if (Tij[i][j] .traf<1.0) Tij[i][j] .traf=1.0
 if (Tij[j][i] .traf<1.0) Tij[j][i] .traf=1.0.
- 15) Add new Tij/Tji into sums, so that sums are kept up to date along the way.
 sumTij[i] += Tij[i][j] .traf
 sumTij[j] += Tij[j][i] .traf.
- 16) Use handshaking to increase sumTij
- 17) Test Convergence
 If sumTij is off by more than 10% for any switch, don't converge; otherwise, set flag to converge. Print progress for each iteration as the total amount of traffic difference between the sumTij's and the offd_traf's.
- 18) Set up for **Step III**.
 Calculate Egress Traffic and print intermediate results.

STEP III

- 1) Perform offd_traf<=>egr_traf equalization. {Note that this step does not use handshaking, so that decreases/increases in Tij are not mirrored for Tji direction. This is why this step is done last and only once}.
- 2) Increase or decrease allocation from i to j, depending on j's balance of offd/egr traffic adjust Tij[i][j] .traf proportionately to offd/egr ratio.
- 3) Impose minimum of 1 erlang between each pair.
- 4) Renormalize Tij so that it sums to offd_traf.
- 5) Impose minimum of 1 erlang between each pair
- 6) Resum sumTij from Tij now that it's normalized.
- 7) Calculate Egress Traffic and print final results
- 8) Print Output TrafDist File

Inputs	none	
Outputs	please see description of output file "mci2lecam file" under the module description section.	
Purpose	to format and print data for input to lecam.c	
Called By	main()	
Calls To	none	
Local Variables		
integer	count, k, l, m, n	loop count variables
Global Variables		
integer	NUMEO	number of end offices
	NUMAT	number of access tandems
	NUMPOP	number of points of presence
	NUMSW	number of switches
Algorithmic Description	This function writes out all output variables to the output file "mci2lecam.step1" for a list of these variables and the file format see the description of the output file under the module description section.	

3.3 sprlive: Build Sprint Live Network and Traffic

Purpose The purpose of this module is to complete the representation of the undamaged Sprint network. This module uses existing publicly available data on that network along with telco engineering and reverse engineering methods to completely represent the Sprint network from the TGs down to the LECS.

This program also allocates traffic from the switches down to the EOs, creating traffic patterns along the way on EO-POP, AT-POP, and EO-AT TGs and builds a traffic matrix. This module is used in conjunction with `sprwdmg` which introduces damage effects into the network data files. The final output of the two step process after the `sprwdmg` module is input into the LECAM module.

Call Syntax `sprlive -k <key file> [mandatories][options]`

<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
<code>-k</code>	<code><keyfile></code>	reads in input file <code><key file></code>
<i>optional;</i>	<i>special syntax:</i>	<i>function:</i>
<code>-o</code>	<code><outfile></code>	reads in output file name. If not specified, default file name is <code>spr2lecam.step1</code>
<code>-t</code>	<code><#></code>	invokes <code>Trafdist()</code> , traffic distribution matrix routine, default setting
<code>-h</code>		invokes new High Usage occupancy and overflow algorithm commands (this setting is now considered the default setting)
<code>-p</code>		High Usage overflow default setting override
<code>-?</code>		user help--prints call syntax and exits without running

example `sprlive -k dplive.key -h` (spaces optional)

**Input

Includes "sprlive.h" Defines global network and traffic variables and constants
 "lecam.h" Defines network sizing constants
 "fileio.c" User-defined I/O functions; see Appendix A

Constants Constants used in sprlive and defined in "sprlive.h":

OVFLW	0.90	Sprint overflows 10% from HU to final
TRKOCC	0.95	HUs are 95% occupied
INTRA	0.0	multiplier for interswitch traffic to add intra
MAX_ITER	100	maximum number of iterations for traffic algorithm
TOLERANCE	0.1	precision level

Constants used in sprlive and defined in "lecam.h":

TRUE	1	true
FALSE	0	false
MAX_AT	1000	maximum number of access tandems
MAX_EO	19250	maximum number of end offices
ATPOPMAX	9	maximum number of POPs a single AT may home to
MAX_POP	575	maximum number of points of presence
MAX_SWITCH	130	maximum number of switches
MAX_LATA	1000	maximum number of LATAs
MAX_REGION	5	maximum number of regions covered by a LATA

Global Variables

global variables defined in "sprlive.h"

integer	KEYTOG	toggle to indicate input 'file name' was read in successfully
	NUMEO	number of end offices
	NUMAT	number of access tandems
	NUMPOP	number of points of presence
	NUMSW	number of switches
	ATPOPSIZE	the number of trunks between the AT and the POP
	HAP[MAX_AT][ATPOPMAX]	number of high usage trunks between the AT and the POP
	AT[MAX_EO]	traffic at the AT
	ATPOP[MAX_EO]	traffic between the AT and the POP
	HUPOP[MAX_EO]	traffic between the high usage AT and the POP
	TYPE[MAX_EO]	type of homing between the AT and the switch
	SW[MAX_EO]	traffic at the switch
	LATA[MAX_EO]	traffic at the LATA
	COC[MAX_EO]	central office code homings
	IMT[MAX_SWITCH][MAX_SWITCH]	matrix of backbone trunk traffic
	SEP[MAX_EO]	size of trunks between EO and POP
	SAP[MAX_AT][ATPOPMAX]	size of trunks between AT and POP
	COCSW[MAX_SWITCH]	matrix of homings between switches and COCs
	PhysDiv[MAX_EO]	physical diversity value for each EO of TYPE = 3
	SW_nlata[MAX_SWITCH]	number of LATAs that a switch serves
	popswitch[MAX_POP]	POP switch homing

D3DONE[MAX_AT] [ATPOPMAX]	a logical control variable to avoid double counting AT to POP trunks groups
TOT_IMT	total number of backbone trunks at the switch
EOLOC[MAX_EO] [2]	location of each EO
ATLOC[MAX_AT] [2]	location of each AT
SWLOC[MAX_SWITCH] [2]	location of each switch
POPLOC[MAX_POP] [2]	location of each POP
EOA	originating end office
EOB	terminating end office
TOTAT	total traffic at the AT
TOTEO	total traffic at the EO
TOTSW	total traffic at the switch
TOTT2	total traffic of Type 2
TOTT3	total traffic of Type 3
real IMTTraf[MAX_SWITCH] [MAX_SWITCH]	traffic between switches
TEP[MAX_EO]	traffic EO to POP
TEA[MAX_EO]	traffic EO to AT
TAP[MAX_AT] [ATPOPMAX]	traffic AT to POP
ACSlec[MAX_SWITCH]	LEC access capacity at the switch. This is the sum of the D3[POP]s for POPs homed to SW. This is a function of TEP and TAP. Alternatively, ACSlec is the sum of AC[k] for all EOs k homed to SW. These two methods should yield the same answer (within rounding). This is computed before damage.
ACS[SW]	This parameter is derived by summing the P.01 engineered traffic on IMTs going into SW, times 0.5 for one-way. This parameter is later decremented in the allocation algorithm, and is thus unsuitable for the calculations that follow that algorithm. ACS is a function of IMTTraf.
ACSiec[MAX_SWITCH]	Exact copy of ACS[SW] , but is not decremented in the allocation algorithm. ACSiec is used to compute ACSPOP. ACSiec is a function of IMTTraf.
AC[MAX_EO]	total access capacity
D3[MAX_POP]	This is the access traffic arriving at POP from the EO-POP and AT-POP TGs homed to it. D3 is a function of TEP and TAP. This is equal to intraswitch plus interswitch traffic at a POP
ACSPOP[POP]	This is the access traffic that POP can offer to SW for transmission across IMTs. This is $D3 * (ACSiec/ACSlec)$, and is written to outfile as the "real" D3, since it more accurately reflects engineered load at a POP. ACSPOP is a function of IMTTraf. It is computed before D3 is decremented for damage, so that it reflects true all-alive engineered traffic. It is equal to interswitch traffic (only) at a POP.
ACSlec[SW]	This is the sum of the D3[POP] s for POPs homed to SW. This is a function of TEP and TAP. Alternatively, ACSlec is the sum of AC[k] for all EOs k homed to SW. This is computed before damage.

	ACPiec[MAX_POP]	access traffic engineered from IEC switches to POP
	PropIntra[MAX_SWITCH]	proportion of intraswitch traffic
	fProp[MAX_SWITCH]	ratio intraswitch traffic to interswitch traffic
	Overflow[MAX_EO]	traffic overflowing AT to POP on high usage trunks
	TOTFO	total focused overload traffic
double	FO[MAX_EO][2]	divided into HU traffic (0) and FINAL traffic (1)
character	swclli[MAX_SWITCH][12]	matrix of clli codes for each switch
	clli[12]	individual clli code
	equip[4]	four character equipment code
	global variables defined in "keyfiles.h"	
FILE	* fileptr	points to an open input file
	* outfile	points to an open output file
	* fptr	points to an open output file
character	eo_file[80]	name of the EO file
	at_file[80]	name of the AT file
	iec_eo_file[80]	name of the IEC EO file
	iec_at_file[80]	name of the IEC AT file
	iec_sw_file[80]	name of the IEC SW file
	iec_pop_file[80]	name of the IEC POP file
	morph_file[80]	name of the morphing file
	swhmg_file[80]	name of the switch homing file
Local		
Variables	Variables local to main()	
extern	character * optarg	a string containing a single command line argument.
integer	optind	the number of single command line arguments to be processed, supplied externally by the operating system
character	c	a command line option character
	outfile[80]	the name of the output file
	line[200]	buffer for parsing a single input line from a file
	livekeyfile[80]	the name of the input key file for the live networks
	** argv[]	an array containing all of the command line arguments
integer	err=0	error flag indicating a problem with the command line arguments
	otog=0	indicates use of the [-o] option (a user supplied output file name)
	ttog=0	command line parameter setting indicates the use of the [-t] option (currently not used)
	htog=0	indicates the [-h] option (use of new high usage rules, this is now the default setting)
	ptog=0	indicates the [-p] option (override use of new high usage overflow rules)
	test	not used

	ovflw_count=0	the number of end offices that overflow from HU to final homing (same as t3_num)
	dummy	used to read in a dummy integer value
	cap	total capacity
	i, j, k, l, m, n, p, pm	loop count variables
	SEP_total=0	sums the number of high usage trunks between EOs and POPs
	argc	the number of command line arguments
structure	AT_hmg[MAX_AT] of type AT_hmg_struct	
	with fields:	
integer	type2	number of Type 2 homing switches
	type3	number of Type 3 homing switches
real	ovflw_total=0	the total amount of traffic which overflows from the high usage trunks
	TEP_total=0	the total amount of traffic between EOs and POPs
	TEA_total=0	the total amount of traffic between EOs and ATs
	wovflw_total=0	the weighted overflow based on access capacity across all EOs
	wovflw_denom=0	the total access capacity across all EOs
	sum2_AC=0	sum of the access capacity for Type 2 switches
	sum3_AC=0	sum of the access capacity for Type 3 switches
Component Functions		
void	Init()	initializes all network variables
	ReadFiles()	reads in each section of the input files specified in the <keyfile>
	Trafdist()	This routine defines the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
	OutWrite()	writes out each section of the output file
	defined in "sprlive.h"	
void	LoadKeyfile()	loads input file names from the <keyfile> specified in the command line
double	ErlangB()	traffic calculator for engineering overflow capacity using ErlangB blocking
	PoissonA()	traffic calculator for for engineering traffic from switchA to switchB and vice-versa
	PoissonAmod()	traffic calculator for engineering traffic from switchA to switchB and vice-versa
	PoissonNmod()	traffic calculator for number of trunks
integer	PoissonN(Ain,Bin)	traffic calculator for number of trunks
	phdiv(eo,at,pop)	determines physical diversity based on co-location

Function Tree

Algorithmic Description

This module completes the representation of the Sprint network and the traffic that is carried on that network. The procedure is to distribute the Sprint traffic down through the local exchange carriers (LEC) in order to build a reasonable model of the network and its relationship to the LECs. A similar process is undertaken with AT&T and Sprint.

Sprint provides the sizes of High Usage trunks (HU) and access tandems (AT) to point-of-presence (POP) trunk groups (TG), which are used to engineer traffic in the LECs. Where homings through an AT are involved, traffic must be allocated down from the AT to the end offices (EO). There are several ways to do this, each with drawbacks and advantages. This module uses the most accurate method where possible; cases where this method breaks down are detected, and a secondary method is used to allocate traffic from these ATs down to their EOs.

The `main()` routine contains the majority of the algorithmic code for this module. After the command line toggles have been interpreted, the `main()` routine begins by passing the `<keyfile>` argument into `LoadKeyfile()`, which reads in the names of the LEC and interexchange (IEC) files. It then calls `Init()`, which initializes all network variables. `Readfile()` is called next to read in all network data. `Main()` then opens the `<outfile>` and proceeds to perform the core of the algorithmic work in this module, in the following order:

- 1) Call `PoissonAmod()` which uses the number of backbone/IEC trunks to compute the backbone traffic across the trunks. Traffic $i \rightarrow j$ is 1/2 load of the combined 2 way trunk group.
- 2) Engineer total interswitch traffic at each switch by summing traffic from all backbone trunks that end at a switch.
Set access traffic = to one half of total traffic
- 3) Use a 3-Pass algorithm to allocate traffic to individual LEC network segments, for 3 Types of LEC Trunk group size homings: **Type 1**, HU-only homings, **Type 2**,

AT-only homings, and **Type 3**, homings that involve an HU overflowing to the AT (final) homing :

In general calculate:

- AC (access traffic offered by an EO)
- TEA (traffic going on the EO-AT TG, if any)
- TAP (traffic going on the AT-POP TG, if any)
- TEP (traffic going on the EO-POP TG, if any).

PASS 1 Engineer the straightforward cases and set up statistics to support the more complex cases.

Type 1. HU-only homing.

Call `PoissonAmod()` to engineer AC directly from the EO-POP TG size, assuming P.01, (1% blocking).
Set EO-POP traffic equal to AC.
De-allocate EO AC from switch (SW) traffic.

Type 2. AT-only homing.

Traffic over AT-only homings cannot be allocated until the effect of overflow from HU trunks is determined. In the first pass we sum up central office codes (COC) for all EOs homed to the same AT-POP TG.

Type 3. HU with AT overflow.

Traffic for HU homings that overflow through the AT is calculated using the methodology shown below. In later passes, it is determined if this method broke down for a particular AT. If so, an alternative algorithm is used.

The preferred algorithm is:

A) Call `PoissonAmod()` to engineer communications sent directly EO-POP (with P.80 blocking on the HU TG meaning the last trunk in the TG is occupied 80% of the time).

B) Call `ErlangB()` to engineer overflow capacity sent first through the AT then to the SW. Traffic overflowing to the AT is computed by offering AC to the HU TG using Erlang B blocking. This Erlang B blockage is used to determine traffic carried on the HU, and traffic that must overflow from the EO to the AT.

C) Compute the running sum of EO-AT traffic for each AT-POP TG to determine if our methodology would create more AT-POP traffic than could be handled by the AT-POP TG. As a precautionary measure, compute the variables required by the backup algorithm: the sum of COCs and overflow-weighted COCs to each AT-POP TG for the **Type 3** homings.

PASS 1.5 This pass only applies to **Type 3** EOs.

No network variables are calculated. Only determines if first-choice numbers in previous pass are valid.

Type 1. HU-only homing. No calculations for this pass.

Type 2. AT-only homing. No calculations for this pass.

Type 3. HU with AT overflow.

Determines whether the first or second-choice algorithm will be used for allocating AT-POP traffic down to EOs. If the first-choice algorithm won't work (i.e. causes AT-POP traffic to be greater than what the AT-POP TG can accommodate), then a flag is set for the next pass, and the **Type 3** overflow-weighted COCs are combined with the **Type 2** COCs to create the total needed by the alternative algorithm.

If the first choice algorithm will work, then the share of AT-POP traffic already allocated to **Type 3** EOs is subtracted from the amount available to be allocated to the **Type 2** EOs that use the same AT.

PASS 2 The second pass allocates traffic to the **Type 2** EOs (AT-only homings) regardless of the method used for **Type 3** traffic allocation. Calculate traffic the **Type 3** EOs for the cases where the alternative allocation algorithm must be used.

Type 1. HU-only homing. No calculations for this pass.

Type 2. AT-only homing.
Use COCs and the AT-POP traffic to engineer the access capacity and the EO-AT traffic and then to the SW.
Calculate AC based on COCs
Allocate traffic AT-POP
Calculate traffic EO-AT
De-allocate AC traffic at the SW

Type 3. HU with AT overflow.
Use second-choice algorithm:

If htoq is set to true

Allocate AT-POP traffic based on overflow weighted COCs

Replace previous values of TEA and AC

De-allocate AC traffic at the SW

else

Allocate AT-POP traffic based on HU overflow weighted COCs

De-allocate AC traffic at the SW

Replace previous values of EO-AT traffic and AC.

At this point all LEC network traffic variables have been engineered and the calculation of Traffic and the determination of Trunks is complete in the LEC.

- 4) Reduce AC by 1/2 to capture access capacity only, assuming access = egress at an EO. Perform this for each EO in the LEC and for each SW in the IEC.
Sum traffic from LECs up to SW (ACS_{lec}).
- 5) For each **Type 3** homing (HU with AT overflow), call `phdiv()` determine physical diversity. (i.e. collocated = not physically diverse; not collocated = physically diverse). This is necessary to determine if physical damage to an AT site will also cause damage to the HUE homing.
- 6) Print ACS, ASCII and ACS_{lec} for each SW
- 7) Compute and print overflow and occupancy summary statistics:
Sum AC for each **Type 2**.
Sum **Type 2** homings.
Verify actual engineered overflow from the HU TG to the POP.
Sum AC for each **Type 3**.
Calculate average and weighted average overflow.
Calculate EO-POP and EO-AT traffic.
- 8) Use ACS_{lec} and results of `phdiv()` to recalculate SW AC. Backbone trunks that connect to a SW with no EO homings should not be included in calculating SW AC. This occurs when a SW is collocated.
- 9) Calculate AT traffic engineered between LEC switches and POP.
Sum HU traffic up to POPs.

Sum AT traffic up to POPs

Switch and Pop variables are now calculated, including versions that include inter-switch traffic only, and versions that include both inter- and intraswitch traffic. From this, the proportion of intraswitch traffic at each switch (PropIntra) is calculated.

- 10) Calculate the amount of inter-switch access traffic at a POP.
Determine iintraswitch traffic.
- 11) Calculate the proportion of intraswitch traffic and set the lowest value of
PropIntra = 0.3
- 12) Calculate one-half the value of : traffic EO to POP and traffic EO to AT.

At this point the calculation of Traffic and the determination of Trunks is completed in the LEC

- 13) If ttog set on then call TrafDist() . This routine defines the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
- 14) Call OutWrite() which formats and writes all variable to the outfile which is a LECAM input file.

Inputs none; operates on global variables

Outputs

global	integer	NUMEO=0	number of end offices
		NUMAT=0	number of access tandems

**Algorithmic
Description**

This function reads in the live network variables from several input files. The input is performed in the following sequence:

- 1) Read in LEC data from IEC EO file which contains homing chains from EO-SW and count number of EOs
- 2) Read in LEC data from the IEC AT (HAP) file which describes AT-POP homings, which may be multiple.
- 3) Read in EO V-H coordinates from the EO file.
- 4) Read in AT V-H coordinates from the AT file.
- 5) Read in Switch V-H coordinates from the IEC Switch file. Also read in and store the CLLI code and the number of LATAs that a switch serves
- 6) Read in POP V-H coordinates from the IEC POP file. Also read in POP switch homing.
- 7) Read the undamaged IMT matrix from the qlink file.

3.3.3 Trafdist function

sprlive module

Inputs	none	
Outputs		
returns	none	
Purpose	Before writing network variables to the final output file, we perform the final major task of SprintLIVE: creation of the backbone traffic distribution. This matrix helps us know how to handle traffic once it travels up from the LEC networks to the IEC toll switch. Specifically, it determines, for a given switch 'i', what proportion of its access traffic goes to each other distant backbone switch 'j'.

Algorithmic Description

The results of `trafdist` go in their own output file, '`trafdist.spr`'. All other network variables are written to the master output file, '`spr2lecam.step1`', which has a multi-section format comprising some header information, and a section for each network variable. The format and contents of this file are described in more detail in the `OUTWRITE ()` function description.

`TrafDist` creates a switch-to-switch traffic distribution file to replace the homomorphism. It outputs this file to '`trafdist.spr`' in the current directory, using the same format as the homomorphism file, so that subsequent code (`sprwdmg`) does not have to be altered to read in a different format.

Step I

In this step, a first approximation of the T_{ij} switch-to-switch matrix is developed. The algorithm first populates T_{ij} pairs for which direct trunk groups exist. (Note: the only T_{ij} pairs are those between class3 switches and two class1's that serve LEC traffic directly). The T_{ij} pairs are populated with the P.01 engineered load, (since Sprint trunks are one-way, this doesn't need to be divided by 2). The T_{ij} entry for the class1 switches is further divided by 3, since by inspecting the data, these two class1 switches (i,j) need about 1/3 of their IMTs to serve their own originating traffic. Since direct trunk groups account for 75% of Sprint's backbone capacity, most of the proportions are calculated this way. Traffic between the remaining 25% of the switch pairs is estimated by using the proportions of access traffic * 0.3, e.g.;

$$T_{ij} = 0.3 * \text{offd}(i) * \text{offd}(j) / (\text{sum of offd}(k) \text{ for all } k \neq i)$$

where $\text{offd}(i)$ = offered traffic of the switch

The 0.3 weighting signifies that since the switch pair was not important enough to have direct trunking, it probably shares less traffic than the average switch pair, which would have a weighting of 1. Since it is safe to assume that switch pairs without direct trunking are in the bottom 25% and probably have little community of interest, then any weighting between 0.2 and 0.5 would suffice to estimate this.

Step II:

Once the matrix is estimated, the access traffic for each switch is summed from the individual T_{ie} elements. The goal of Part II is to normalize this $\text{sum}T_{ij}$ to offd_traf , the offered traffic of the switch. Offd_traf for switch i is:

$$\text{Offd_traf}[i] = \text{ACSlec}[i] * (1 - \text{PropIntra}[i])$$

Since Sprint's IMT trunking is much greater than its LEC access traffic, this is a significant step. An iterative approach is employed, whereby a switch whose sumTij estimate is greater than offd_traf systematically "negotiates" with all other switches who have the same problem. For example, if switch i and j both have sumTij greater than their respective offd_traf s, they decrease their Tij/Tji pairs by the average of $(\text{offd_traf}[i] / \text{sumTij}[i])$ and $(\text{offd_traf}[j] / \text{sumTij}[j])$. Thus each switch decrease its traffic by the same amount, avoiding cases where $\text{Tij} \gg \text{Tji}$, or vice versa. This process is also done for cases where $\text{sumTij} < \text{offd_traf}$, and iterations continue until every sumTij is within 10% of its offd_traf or the max of 100 iterations is performed.

Step III:

At this point, we ensure that $\text{offd_traf} = \text{egr_traf}$ at a switch:

*Suppose switch i is sending traffic to a switch j , which is getting too much egr_traf . Then Tij is reduced to $\text{Tij} * (\text{offd_traf}[j] / \text{egr_traf}[j])$, and the excess = $\text{Tij} * (1 - \text{offd}/\text{egr})$ is redistributed to all other switches proportionally. The same holds true for switches that don't get enough egress traffic.*

Closing comments: When this algorithm converges, two things should be true:

1. sumTij nearly equal to offd_traf for all switches
2. offd_traf nearly equal to egr_traf for all switches

It may be the case that Tij 's for some pairs exceed their direct trunking by as much as two times, which is far off from the original estimate of P.01. However, the algorithm works because Sprint's IMT capacity is \gg LEC access traffic to Sprint, and so there is a good deal of room for these cases to overflow their traffic safely through hierarchical overflow routes without causing blockage. In fact it should be stressed that this algorithm is possible only because of this safety margin, so that a rough approximate that satisfies (1) and (2) above is all that is necessary. The other aspect that makes this algorithm work is that it starts with Sprint's own backbone trunking, and only alters traffic patterns proportionately and evenly in each step. Thus, the traffic patterns suggested by the direct trunk groups should be preserved within an order of magnitude.

Presented below is a step by step description of the above algorithm. After declaring and initializing local declarations the following steps are executed.

Preparation for Step I

- 1) Open and read switch homing file. This file gives the homing for class1 switches for each class3 switch. A class1 switch has a homing equal to a blank string.
- 2) Set class attribute of switch to **Type 1** or **Type 3**
- 3) Compare order of $\text{sw}[i].\text{clli}$ and $\text{swclli}[i]$, as a cross-check
- 4) Load clli index field
- 5) Analyze trunking from qlink file (IMT).
{This code was developed as a diagnostic of Sprint's backbone, and is not necessary for the TrafDist algorithm that follows. It determines the proportion of Sprint's backbone capacity used for directly connected class3 switch pairs}.
- 6) Keep track of switch pairs that are not directly connected.
- 7) Print resulting summary stats

STEP I TrafDist algorithm starts here

- 1) Populate T_{ij} matrix with traffic
- 2) If **Type 1** (direct trunking exists):
Then size traffic to P.01 over trunk $IMT[i][j]$. Check for class1 serving LEC traffic and adjust T_{ij} in this case.
- 3) If **Type 2** (i.e., no direct trunking exists):
Then Compute opposite direction, as long as it doesn't have a direct trunk group either.
Report Results

STEP II

- 1) Iterate until offered traffic ($offd_traf$) and $sumT_{ij}$ agree.
- 3) Use handshaking to reduce $sumT_{ij}$ towards $offd_traf$.
- 4) Look for another switch that also has a value of $sumT_{ij}$ that is too high, so that switches i and j can mutually lower traffic to each other by the same proportion.
- 5) Calculate proportion for switch i and j , and use average as proportion for mutually reducing T_{ij}/T_{ji} .
- 6) Discount old T_{ij}/T_{ji} from sums:
 $sumT_{ij}[i] -= T_{ij}[i][j].traf$
 $sumT_{ij}[j] -= T_{ij}[j][i].traf.$
- 7) Calculate new T_{ij}/T_{ji} as proportionately smaller:
 $T_{ij}[i][j].traf = min_prop * T_{ij}[i][j].traf$
 $T_{ij}[j][i].traf = min_prop * T_{ij}[j][i].traf.$
- 8) Impose minimum of 1 erlang between each pair:
 $if (T_{ij}[i][j].traf < 1.0) T_{ij}[i][j].traf = 1.0$
 $if (T_{ij}[j][i].traf < 1.0) T_{ij}[j][i].traf = 1.0.$
- 9) Add new T_{ij}/T_{ji} into sums, so that sums are kept up to date along the way:
 $sumT_{ij}[i] += T_{ij}[i][j].traf$
 $sumT_{ij}[j] += T_{ij}[j][i].traf.$
- 10) Use handshaking to increase $sumT_{ij}$ look for another switch that also has $sumT_{ij}$ too high, so that switches i and j can mutually lower traffic to each other by the same proportion.
- 11) Calculate proportion for switch i and j , and use average as proportion for mutually reducing T_{ij}/T_{ji}
 $min_prop = offd_traf[i] / sumT_{ij}[i]$
 $min_test = offd_traf[j] / sumT_{ij}[j]$
 $min_prop = (min_test + min_prop) / 2.0.$
- 12) Discount old T_{ij}/T_{ji} from sums
 $sumT_{ij}[i] -= T_{ij}[i][j].traf$
 $sumT_{ij}[j] -= T_{ij}[j][i].traf.$
- 13) Calculate new T_{ij}/T_{ji} as proportionately smaller

```
Tij[ i][ j] .traf = min_prop * Tij[ i][ j] .traf.
Tij[ j][ i] .traf = min_prop * Tij[ j][ i] .traf.
```

- 14) Impose minimum of 1 erlang between each pair

```
if (Tij[ i][ j] .traf<1.0) Tij[ i][ j] .traf=1.0
if (Tij[ j][ i] .traf<1.0) Tij[ j][ i] .traf=1.0.
```
- 15) Add new Tij/Tji into sums, so that sums are kept up to date along the way.

```
sumTij[ i] += Tij[ i][ j] .traf
sumTij[ j] += Tij[ j][ i] .traf.
```
- 16) use handshaking to increase sumTij.
- 17) Test Convergence

If sumTij is off by more than 10% for any switch, don't converge; otherwise, set flag to converge. Print progress for each iteration as the total amount of traffic difference between the sumTij's and the offd_traf's.
- 18) Set up for Step III.

Calculate Egress Traffic and print intermediate results.

STEP III

- 1) Perform offd_traf<=>egr_traf equalization. {Note that this step does not use handshaking, so that decreases/increases in Tij are not mirrored for Tji direction. This is why this step is done last and only once}.
- 2) Increase or decrease allocation from i to j, depending on j's balance of offd/egr traffic. Adjust Tij[i][j] .traf proportionately to offd/egr ratio.
- 3) Impose minimum of 1 erlang between each pair
- 4) Renormalize Tij so that it sums to offd_traf
- 5) Impose minimum of 1 erlang between each pair
- 6) Resum sumTij from Tij now that it's normalized.
- 7) Calculate Egress Traffic and print final results
- 8) Print Output TrafDist File

Inputs	none
Outputs	please see description of output file "spr2lecam file" under the module description section.
Purpose	to format and print data for input to lecam.c
Called By	main()
Calls To	none
Local Variables	
integer	count, k, l, m, n loop count variables
Global Variables	This routine define the community of interest weighting that describes how much or how little traffic a switch will send to another switch due to their proximity.
Algorithmic Description	This function writes out all output variables to the output file "spr2lecam.step1" for a list of these variables and the file format see the description of the output file under the module description section.

3.4 tami: Master Loop for the TAMI model

Purpose This is the master loop for the TAMI model. It forms the Monte Carlo loop around the data preparation and LECAM/QTCM modules. It calls each of the modules, passing along the appropriate command line parameters. The keyfile (-k) contains all of the necessary data files to run TAMI. Results of each Monte Carlo bin are stored in TAMI.RESULTS.binX, where X is replaced with the current bin number. Bins may either be Monte Carlo or use a single damage vector. Bin sizes are defined in the keyfile.

Call Syntax tami -k <key file> [options]

<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
-k	<key file>	reads in input file <key file>
<i>options:</i>	<i>special syntax:</i>	<i>function:</i>
-c		indicates use of CSI file.
-d		turns dynamic overload control on or off
-m	<#>	offered traffic multiplier
-e	<1> or <2>	invokes early-post-disaster rules (early1 or early2 only)
-a		disables alternate routing scheme for AT&T
-v		invokes INITPREV in LECAM which initiates LECAM with previous values
-n		invokes the use of the NS/EP matrix
-r		indicates regional focused overload
-x		cancels print results in LECAM
-l		turns on LEC TCR in selected LATAs
-?		user help—prints call syntax and exits without running

example tami -k dplive.key -m 10 -e 1 -v (spaces optional)

	with fields:	
	character	BinList[MAXBIN] .name[50]
	integer	BinList[MAXBIN] .ONOFF BinList[MAXBIN] .maxiter
real	TMULT	Offered traffic multiplier - default is 1x

Local Variables

	Variables local to main()	
extern	character *optarg	a string containing a single command line argument.
integer	optind	the number of single command line arguments to be processed, supplied externally by the operating system
character	ch	a command line option character
	line[200]	buffer for parsing a single input line from a file
	temp[20]	used to parse a line
	TMULTSTR[10]	holds offered traffic multiplier for character to integer conversion
	keyfile[80]	holds the name of the input key file
	**argv[]	an array containing all of the command line arguments

integer	err=0	error flag indicating a problem with the command line arguments
	argc	the number of command line arguments
	i, j	loop counter variables
	current_bin	
	vector_offset	
	OPTOG	indicates command line options
FILE	*fptr	file pointer
Component Functions		
void	LoadKeyfile()	loads input file names from the <keyfile> specified in the command line
	ITOA()	converts from integer to a character variable
	GenQTCM()	runs the QTCM filters to generate the QTCM input files
	GenLECAM()	runs the data preparation filters to generate the LECAM input files
	monte_carlo()	runs an individual bin loop

Function Tree

Algorithmic Description

This is the master loop for the TAMI model. It forms the Monte Carlo loop around the data preparation and LECAM/QTCM modules. It calls each of the modules, passing along the appropriate command line parameters. The keyfile (-k) contains all of the necessary data files to run TAMI. Results of each Monte Carlo bin are stored in TAMI.RESULTS.binX, where X is replaced with the current bin number. Bins may either be Monte Carlo or use a single damage vector. Bin sizes are defined in the keyfile.

After the command line toggles have been interpreted, the main() routine begins by passing the <keyfile> argument into LoadKeyfile(), which reads in the number and names of the IEC networks being used and the identity of the bins. Next it checks for the following options to see if they have been set 'on/off' for logical variables or given a value for integer variables: DOC, TMULT, EARLY, CSI, ALTOFF, NSEPMAT, RTOG, LECTCR, INITPREV, CANCELEPR. It then begins looping through all of the various bins as specified in NumBins. Each bin is then passed as an argument to monte_carlo(). Monte_carlo() runs an individual bin loop using GenQTCM() and GenLECAM(). The calls Init(), which initializes all network variables. Readfile() is called next to read in all network data. Main() then opens the <outfile> and proceeds to perform the core of the algorithmic work in this module.

Inputs

character keyfile[]

Outputs

returns no formal returns

global	character	SwitchDmgFile[]	the name of the IEC switch damage files
		QlinkFile[][]	the name of the IEC qlink files
		SwHmgFile[]	the name of the MCI Switch Homing file
		CSIfile[]	the name of the CSI Damage file

Purpose This routine loads file names from the keyfile specified in the command line of tami.c.

Called By main()

Calls To none

Local Variables

integer	i, j	loop count variables
	pos	indicates line position in the output character variables
character	line[100]	used for parsing the key file
	temp[10]	used for parsing the key file
	temp2[100]	used for parsing the key file
file	* fptr	points to an open file

Global Variables

character	att	IEC toggle
	mci	IEC toggle
	spr	IEC toggle

Algorithmic Description

- 1) Open the file keyfile as read only and assign it to * fptr.
- 2) Skip the comment lines in the file.
- 3) Find the IEC section of the file, determine which IECs are being used, and set toggles on.
- 4) Load damage bins.
 For each line in the keyfile which contains a damage bin read the line and determine the number of bin iterations and the names of the bins.
 For each line in the keyfile which contains LEC information check for:
 a regional overload file.
 a LECTCR file.
 a NSEP file.

- 5) Load IEC carrier file names to specific line positions in the following files for each carrier:
- | | |
|---------|--------------------------------------|
| AT&T: | SwitchDmgFile, CSIfile, QlinkFile; |
| MCI: | SwitchDmgFile, SWHmgFile, QlinkFile; |
| Sprint: | SwitchDmgFile, QlinkFile |

Inputs

integer	c	any integer value up to 4 digits in length
---------	---	--

Outputs

returns	character	character representation of an integer
---------	-----------	--

Purpose This routine converts an integer to a string. It accepts any integer up to 9999, converts each digit to a character, and returns a pointer to the resulting string

Called By main()
monte_carlo()
GenQTCM()
GenLECAM()

Calls To none

Local Variables

character	s[10]	holds the return value
-----------	--------	------------------------

Global Variables none

Algorithmic Description This function returns the character representation of an integer input by using the standard c utility function sprintf() .

Inputs

integer	bin	damage bin
	vector_offset	used to parse a line of input
	maxiter	maximum number of damage vectors for sampling
character	name[]	holds name of output file
	keyfile[]	holds name of input file

Outputs**Purpose**

Called By main()

Calls To GenQTCM()
GenLECAM()
ITOA()
system()

Local Variables

integer	count	loop count variable
	mcbin	monte carlo bin
	target	target number of iterations
	a	used to parse a line of input
	z	used to parse a line of input
	c1	counter variable
	c2	counter variable
real	error	error level
char	temp[200]	used to hold a line of input
	line[100]	used to hold a line of input
	temp2[100]	used to hold a line of input
	ch	used as a flag for the input file data
FILE	*fptr	points to an open file
	*csiptr	points to a csi file
	*outptr	points to an output file

Global Variables

none

Algorithmic Description

This routine runs an individual bin loop. This bin may either be a Monte Carlo bin requiring multiple LECAM runs, or a single damage bin requiring only one LECAM run. Results of each bin are written to TAMI.RESULTS.bin#, where # is the number of the specific bin being run.

- 1) Initialize loop variables. Begin by sampling 3 Monte Carlo runs and adding more as necessary. If the maximum number of damage vectors in this bin equals 1, then

it is assumed to be a single static damage vector (i.e., non-Monte Carlo) and is calculated by itself. Set the Monte Carlo flag (mc) accordingly: 1=monte carlo, 0=static.

- 2) Store each iterations TAMI.lecamlog file in a running file. At the end, copy this running file and the final TAMI.tally file into a file specifically for this iteration.
- 3) Loop while haven't done enough runs and still have more vectors to sample.
- 4) Call GenQTCM()
- 5) Call GenLECAM()
- 6) Cut current CSI damage vector for LECAM
- 7) Merge the data preparation files using a command line system call.
- 8) Run LECAM using a command line system call.
- 9) Keep stats on all blockages calculated, but test convergence on Bpots. The keepstats module will tabulate all BIGB* variables and will echo the error of BIGBPOTS to the screen for convergence testing below.
- 10) Add the TAMI.lecamlog file to TAMI.runstore with a header.
- 11) End of the Monte Carlo sampling loop.
- 12) Store the TAMI.runstore and final TAMI.tally in a file for this bin.
- 13) Print results.

Inputs

integer	vector	holds a single damage vector
character	keyfile	input data file

Outputs see input files for QTCM in the QTCM Programmers Manual; Reference 2

Purpose This routine runs the QTCM filters to generate the QTCM input files.

Called By monte_carlo()

Calls To ITOA()
system()

Local Variables

integer	pos	used to parse the input file
character	temp[100]	used to parse the input file
FILE	*fptr	points to the input file

Global Variables

none

Algorithmic Description

This routine runs the QTCM filters to generate the QTCM input files.

- 1) Run all 3 qtrans. These files will have Section 7
- 2) start in matrices at position 0
- 3) Run each qtrans specified by the IEC toggles
- 4) If MCI is being run then also run mkroun()
- 5) If MCI is being run then also run qmodmci()
- 6) Rename qtrans() files for AT&T and Sprint
- 7) Rename mkroun() file for MCI

Inputs

integer	vector	holds a single damage vector
character	keyfile	input data file

Outputs see input files for lecam.c, Section 3.11

Purpose This routine runs the data preparation filters to generate the LECAM files

Called By monte_carlo()

Calls To ITOA()
system()

Local Variables

character	temp[100]	used to piece together a command line for running a system command
	TAIL[150]	used to parse data from the keyfile

Global Variables none

Algorithmic Description This routine runs the data preparation filters to generate the LECAM files

3.5 mkROUT: derive QTCM input file for MCI

Purpose	This module determines end-to-end connectivity through MCI's hierarchical backbone.		
Call Syntax	mkROUT -k <key file> [options]		
	<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
	-f	<file list>	reads in input files <file list>
	-d	<1>, <2>, ..., <99>, <100>	reads in damage iteration. Must be between 1 and 100 inclusive.
	<i>options:</i>	<i>special syntax:</i>	<i>function:</i>
	-?		user help—prints call syntax and exits without running
example	mkROUT -f sw_fl lk_fl q_fl out_fl -d 50 (spaces optional)		
Input Files	The files listed below are input through a command line option, formats and explanation can be found in the QTCM Programmers Manual; Reference 2		
	mainfile	file holding list of input file names	
	swfile	switch input file	
	linkfile	linking input file	
	qtcmlfile	qtcml input file	
Output Files	outfile	This file contains the results of the MCI QTCM template, with hierarchial routing, output file	
	format	see QTCM Programmers Manual; Reference 2	
	example		
Includes	<stdio.h>	Standard 'c' defined I/O functions	
	<stdlib.h>	Standard 'c' defined functions	
	<string.h>	Standard 'c' defined string functions	
	"fileio.c"	User-defined I/O functions	
Constants	SWITCH_MAX	150	maximum number of switches
	CLLI_LNG	5	maximum clii code length
	CL_13_MAX	1000	maximum number of switch pairs between class1 and class3 switches
	CL_33_MAX	8000	maximum number of switch pairs between class3 and class3 switches
	CL_11_MAX	100	maximum number of switch pairs between class1 and class1 switches
	LINE_LENGTH	200	maximum line length
	SW_REC_LEN	9	switch record length

Global Variables

integer	dmg_iter	number of iterations
	num_sw	number of switches
	num_11=0	number of class1 to class1 switch pairs
	num_13=0	number of class1 to class3 switch pairs
	num_33=0	number of class3 to class3 switch pairs
	nroute[SWITCH_MAX][SWITCH_MAX][8][2]	number of possible routes between 2 switches
character	line[LINE_LENGTH]	length of input line
structure	sw of type sw_struct	
	with fields:	
	integer class	switch class
	cl1_idx	index of the class1 switch, from 1,n
	character cli	switch cli code
	class1	switch class
structure	link_struct of type link_struct	
	with fields:	
	integer sw1	originating switch
	sw2	terminating switch
link_struct	c11[CL_11_MAX]	vector of class1 to class1 switch pairs
	c13[CL_13_MAX]	vector of class1 to class3 switch pairs
	c33[CL_33_MAX]	vector of class3 to class3 switch pairs
FILE	*mainfile	points to the input file containing the names of the files needed in this routine
	*swfile	points to the name of the switch file
	*linkfile	points to the name of the link file
	*qtcmlfile	points to the name of the qtcml data file
	*outfile	points to the name of the output routing file

Local Variables

Variables local to main()

extern	character	*optarg	a string containing a single command line argument.
	integer	optind	the number of single command line arguments to be processed, supplied externally by the operating system
character	ch		a command line option character
	filelist[80]		holds the name of the input key file
	**argv[]		an array containing all of the command line arguments
integer	tog_err=0		error flag indicating a problem with the command line arguments
	tog_filelist=0		error flag indicating a problem with the command line filelist argument

tog_dmg_iter=0	error flag indicating a problem with the command line damage iteration argument
argc	the number of command line arguments

Component Functions

openfiles()	loads input file names from the <filelist> specified in the command line
loadswitches()	loads input switch data
loadlinks()	loads input link data
initroute()	initializes traffic routes
process_routes()	processes traffic routes
push_gen()	determines alternate traffic routes
push_13()	not used

Function Tree

Algorithmic Description

This module is used solely to complete the network representation for the hierarchial MCI network. After declaring functions, global and local variables the following steps are executed:

- 1) Read in and check validity of command line arguments.
- 2) Open switch and link input files and routing table output file, call openfiles().
- 3) Load switch records, call loadswitches().
- 4) Load link records, call loadswitches().
- 5) Initialize routing table, call initroute().
- 6) Process routing table, call process_routes().
- 7) Output routing table, call outwrite().
- 8) Close all files.

Inputs

character *files pointer to a file list

Outputs

returns no formal returns

FILE	*mainfile	points to the input file containing the names of the files needed in this routine
	*swfile	points to the name of the switch file
	*linkfile	points to the name of the link file
	*qtcmlfile	points to the name of the qtcml data file
	*outfile	points to the name of the output routing file

Purpose This routine loads file names from the input file specified in the command line of mkROUT.c.

Called By main()

Calls To none

Local Variables

character tempfile[80] used for parsing the input file

Global Variables none

Algorithmic Description

- 1) Open the input file files as read only and assign it to mainfile.
- 2) Scan the first line of mainfile for the name of the switch file, open it as read only and assign it to swfile.
- 3) Scan the next line of mainfile for the name of the link file, open it as read only and assign it to linkfile.
- 4) Scan the next line of mainfile for the name of the qtcml file, open it as read only and assign it to qtcmlfile.
- 5) Scan the next line of mainfile for the name of the output file, open it as write only and assign it to outfile.

Inputs	none	
Outputs		
structure	sw of type sw_struct	
	<i>with fields:</i>	
	integer	class switch class
		cll_idx index of the class1 switch, from 1,n
	character	clli switch clli code
		class1 switch class
returns	no formal returns	
Purpose	This routine loads the class and index value for each switch pair	
Called By	main()	
Calls To	none	
Local Variables		
	integer	i, j loop count variables
		len length of a line of input from the switch file
Global Variables		
	character	line[LINE_LENGTH] length of input line
Global Constants	SW_REC_LEN	length of a switch record
Algorithmic Description	<ol style="list-style-type: none"> 1) Initialize first record from the swfile 2) Process the switch clli codes and switch class, record by record 3) Keep track of the number of switches. 	

Inputs	none		
Outputs			
structure	sw of type sw_struct with fields:		
	integer	class	switch class
		cl1_idx	index of the class1 switch, from 1,n
	character	clli	switch clli code
		class1	switch class
structure	link_struct of type link_struct with fields:		
	integer	sw1	originating switch
		sw2	terminating switch
link_struct	c11[CL_11_MAX]		vector of class1 to class1 switch pairs
	c13[CL_13_MAX]		vector of class1 to class3 switch pairs
	c33[CL_33_MAX]		vector of class3 to class3 switch pairs
returns	no formal returns		
Purpose	to parse each record of the input file into 2 index values		
Called By	main()		
Calls To	none		
Local Variables			
integer	i	loop count variable	
	idx1	first switch index	
	idx2	second switch index	
	dmg	switch damage value, 0 or 1	
	num_alive	number of surviving switches	
	j	loop count variable	
	found	used to determine uniqueness of swith pairs	
Global Variables			
integer	num_11=0		number of class1 to class1 switch pairs
	num_13=0		number of class1 to class3 switch pairs
	num_33=0		number of class3 to class3 switch pairs
character	line[LINE_LENGTH]		length of input line

**Algorithmic
Description**

- 1) Parse each record of the input link file into 2 index values for each link between switch pairs and the damage value associated with that pair, 0 or 1.
- 2) If no damage, then add the switch index to the appropriate case:
 - class1--> class1
 - class1--> class3
 - class3--> class3
- 3) In each case only add unique values to switch index lists
- 4) Print out switch statistics.

3.5.4	initroute	function	mkroute	module
-------	-----------	----------	---------	--------

Inputs	none		
Outputs			
integer	nroute[][][][]		number of possible routes between 2 switches
returns	no formal returns		
Purpose	to initialize all traffic routes in mci		
Called By	main ()		
Calls To	none		
Local Variables			
integer	i , j , k		loop count variables
Global Variables	none		
Global Constants	SWITCH_MAX	150	maximum number of switches
Algorithmic Description	This function initializes all values of nroute for each switch pair with two values: 99 and 0.		

Inputs	none	
Outputs		
structure	sw of type sw_struct with fields:	
	integer	class switch class
		cll_idx index of the class1 switch, from 1,n
	character	clli switch clli code
		class1 switch class
structure	link_struct of type link_struct with fields:	
	integer	sw1 originating switch
		sw2 terminating switch
link_struct	c11[CL_11_MAX]	vector of class1 to class1 switch pairs
	c13[CL_13_MAX]	vector of class1 to class3 switch pairs
	c33[CL_33_MAX]	vector of class3 to class3 switch pairs
returns	no formal returns	
Purpose	to process the initialized traffic routes in mci	
Called By	main()	
Calls To	push_gen()	
Local Variables		
integer	i, j, k	loop count variables
Global Variables		
integer	num_11=0	number of class1 to class1 switch pairs
	num_13=0	number of class1 to class3 switch pairs
	num_33=0	number of class3 to class3 switch pairs
Algorithmic Description	<p>This function process the traffic routes for each switch pair based on the classes of the two switch pairs:</p> <ul style="list-style-type: none"> • class1-->class1 • class1-->class3 • class3-->class3 <p>1) Process class3-->class3 direct routes</p> <p>2) Process class3-->class3 via routes both homed to the same class1</p>	

- 3) If two class3 switches share same class1, and the class1 is the home class1 for one of them, then process valid class3--> class3 via route
- 4) Process class3-->class3 via routes each homed to a unique class1
- 5) If two different class3 switches have links to two different class1 switches, and if the class1 switches are the home switches of their respective class3 switches, then process valid class3--> class3 route. In other words, there is a class3-->home class1-->home class1'-->class3' route
- 6) Check for existence of class1-->class1' link.
- 7) Process 2 cases where POPs home directly to a class1 switch. In these cases, a class1 must be able to route to class 3 and other class 1 switches.
- 8) Process class1-->class1 direct routes
- 9) Process class1-->class1-->class3 direct routes
- 10) If a class3 goes to its home class 1, and this class 1 is connected to another class 1, then process valid class1-->class1'-->class3' route
- 11) Class1 given by c11[k].sw1 is the home class1 for class3 given by c13[i].sw2.

Inputs

integer	A	originating switch
	Z	terminating switch
	via	via switch
	hops	number of switches in between

Outputs

integer	nroute[][][][]	number of possible routes between 2 switches
---------	--------------------	--

returns	no formal returns
---------	-------------------

Purpose	This function exchanges an alternate route for a more direct route
----------------	--

Called By	process_routes()
------------------	------------------

Calls To	none
-----------------	------

Local Variables

integer	done	logical completion flag
	i	loop count variable

Global Variables

none

Algorithmic Description

This function exchanges an alternate route for a more direct route.

Inputs

FILE *qtcMfile points to the name of the qtcM data file

no formal inputs

Outputs

FILE *outfile points to the name of the output routing file

returns no formal returns

Purpose This function writes the qtcMfile into the outfile

Called By main()

Calls To none

**Local
Variables**

integer	m1	loop counter variable
	m2	loop counter variable
	m3	loop counter variable
	sect3_flag=0	output file flag
	sect4_flag=0	output file flag

**Global
Variables**

character line[LINE_LENGTH] length of input line

**Algorithmic
Description**

This function writes the qtcMfile into outfile until SECTION 03 of the qtcM file is reached. It then proceeds to position the qtcMfile at SECTION 04, and then writes the qtcMfile into outfile from SECTION 04 to EOF.

3.6 qtrans_gen: Generate QTCM Files

Purpose	To create a qcm input file from the qswitch and qlink file format used for the ncam to qcm conversion process	
Call Syntax	qtrans_gen.f	
example	qtrans_gen.f	
Input Files	Descriptions of the input file can be found in QTCM Programmer's Manual; Reference 2. qlink.iec switch_iec.data.dmg	
Output Files	Descriptions of the output file can be found in QTCM Programmer's Manual; Reference 2. outfile This file contains the results of output file	
Includes	none	
Constants	none	
Global Variables	Definitions of the global variables can be found in QTCM Programmer's Manual; Reference 2.

**Algorithmic
Description**

This module is used to produce a qtcn input data file and is coded in FORTRAN

- 1) Open user-named input switch, span files and output files.
- 2) Calculate number of iterations in switch file and Cross check with the number of iter's in span file.
- 3) Give option for directionality (mci=oneway, att & spr=bidirect).
- 4) Give option to ignore damage (sets flag so that section 9 is given default values from init).
- 5) Read in desired iteration from user.
- 6) Calculate the number of records in the switch file. This number is the number of nodes (nnod).
- 7) Prompt for an average link size to be used as a default if 9999 is read in for link size.
- 8) Call init.
- 9) Output header.
- 10) Output general data.
- 11) Calculate qtcn data from ncam data.
- 12) Calculate damaged switches—section 9.2.

- 13) Calculate trunk capacity—section 6.2.
- 14) Test for damage to link or either endpoint.
- 15) Set damaged trunk capacity—section 9.4.
- 16) Derive section 4, 5.2, 5.4 and 7 from section 6.2 note: section 7 is derived to have a “trickle current”. This is used to get the ppmeanfile for mci as input into “mciwdmg”.
- 17) Output network cost and distance matrices.
- 18) Write routing table.
- 19) Write minimum group size.
- 20) Output mandatory connectivity arrays.
- 21) Output trunk size arrays.
- 22) Write offered load.
- 23) Scale offered load if necessary.
- 24) Write switch details.
- 25) Output damage and preferential routing data.
- 26) Write out completion message.
- 27) Format statements

3.7 attwdmg: Pre-process Damaged AT&T Network and Traffic

Purpose This module performs the data preparation calculations required to assess the affects of damage to the LEC homing chains and end-to-end traffic matrix for the AT&T network. Many of the engineered traffic variables computed by `attlive` are adjusted to reflect post-damage engineered traffic under Early and Late scenarios. For a regional analysis, this module computes the focused overload offered load matrix through AT&T. The output file from this module is merged with the other IEC files in the merge module before being input into the `lecam` module.

Call Syntax `attwdmg -k <key file> [options]`

mandatory:

`-d` use damage vector <number> for this run
`-k` reads in input file <key file>

options:

`-b` blast-type damage: use physical diversity model for HU damage
`-e` specify early scenario <1> or <2>
`-i` no longer used
`-r` reads in regional overload input file <reg file>
`-s` specify non-default random number generator stream using <stream> from 1 to 15
`-?` user help—prints call syntax and exits without running

example `attwdmg -k tamirun.key -d5`

**Input
Files**

The list of input files required by `attwdmg` is supplied in the keyfile. See Appendix B (TAMI keyfile description) for these files.

reg file

In addition to the files in the keyfile, for a regional overload run, the `-r` option will specify a regional overload file, <reg file>. The first line of this file specifies the default (Region 0) overload. Unless specified in later regions, all LATAs will be overloaded based on this default. The second line defines Region 1 and its overload value. The next line contains a list of space-separated LATA numbers that are members of Region 1. Subsequent regions are defined similarly, up to a maximum of five regions.

format

`R0, <region overload>` default region line
`<Region number>, <region overload>`
subsequent region line (c2, 1x, f)

`<LATA number>, . . . , <LATA number>` with associated LATAs
(c3, 1x, . . . , i3, 1x, i3)

example

`R0 1.25` defines 1.25 overload for default LATAs
`R1 5.0` defines 5.0 overload for region 1 LATAs
`132 133 134` region 1 LATAs defined here as a list
`R2 10.0` defines 10.0 overload for region 2 LATAs
`251 291 237 252` region 2 LATAs defined here as a list

**Output
Files**

`att2lecam.out`—multisection output file described in function `Outwrite`

Includes	"fileio.c"	includes input/output utility functions—see Appendix A
	"lecam.h"	defines lecam constants and variables—see Section 3.11
	"waglib.h"	defines random number generator functions, constants, and data structures—not used
Constants	MAX_BIN 3	Not used
	NUM_TEMP 25	Number of sections in output file
	TEST_SW #	Number of a switch for which debug statements will be printed

constants defined in lecam.h (network sizing variables) and used in attwdmg:

TRUE	1	
FALSE	0	
MAX_AT	1000	Maximum number of ATs in network
MAX_EO	19250	Maximum number of EOs in network
ATPOPMAX	9	Maximum number of POPs a single AT may home to
MAX_POP	575	Maximum number of POPs in network
MAX_SWITCH	130	Maximum number of IEC switches in network
MAX_LATA	1000	Maximum number of LATAs
MAX_REGION	5	Maximum number of regions defined for regional overload

Global Variables

FILE	*inptr	File pointer for an input file
	*outptr	File pointer for the output file
	*fptr	File pointer for any file
integer	KEYTOG	toggle for -k option
	rtog	toggle for -r option
	NUMEO	number of EOs in network
	NUMAT	number of ATs in network
	NUMPOP	number of POPs in network
	NUMSW	number of backbone switches in network
	NUMREGIONS	number of regions defined for regional overload
	ATPOPSIZE	maximum number of AT-POP homing segments
	HAP[MAX_AT][ATPOPMAX]	AT-POP homings
	AT[MAX_EO]	homed AT for an EO
	ATPOP[MAX_EO]	homed POP through the AT for an EO
	HUPOP[MAX_EO]	homed high-usage POP for an EO
	SW[MAX_EO]	homed IEC switch for an EO
	TYPE[MAX_EO]	homing type for an EO
	LATA[MAX_EO]	LATA designation for an EO
	popswitch[MAX_POP]	homed IEC switch for POP
	IMT[MAX_SWITCH][MAX_SWITCH]	matrix of IMT TGs between IEC switches
	IMT2[MAX_SWITCH][MAX_SWITCH]	copy of IMT matrix used for data checking purposes
	IMTdam[MAX_SWITCH][MAX_SWITCH]	damaged IMT matrix
	SUM_IMT[MAX_SWITCH]	total IMT TGs originating or terminating at each IEC switch
	SAP[MAX_AT][ATPOPMAX]	size of AT-POP TG for each POP homed to AT
	SEP[MAX_EO]	size of the direct EO-POP TG, if exists

	PhysDiv[MAX_EO]	0/1 indication of whether the HU TG, if existing, is physically diverse from the AT
	EOalive[MAX_EO]	0/1 indication of survival of EO
	ATalive[MAX_AT]	0/1 indication of survival of AT
	POPalive[MAX_POP]	0/1 indication of survival of POP
	SWalive[MAX_SW]	0/1 indication of survival of IEC switch
	EOATalive[MAX_EO]	0/1 indication of survival of EO-AT span
	ATPOPalive[MAX_AT][ATPOPMAX]	0/1 indication of survival of AT-POP span
	EOPOPalive[MAX_EO]	0/1 indication of survival of EO-POP span
	POPSwalive[MAX_POP]	0/1 indication of survival of POP-SW span
	LReg[MAX_LATA]	Indicates which Region each LATA is in
	EOReg[MAX_EO]	Indicates which Region each EO is in
float	TAP[MAX_AT][ATPOPMAX]	traffic engineered for SAP TGs
	TEP[MAX_EO]	traffic engineered for SEP TGs
	TEA[MAX_EO]	traffic engineered between EO and AT
	ACSlec[MAX_SWITCH]	traffic offered from LEC to each IEC switch
	ACSlec_live[MAX_SWITCH]	traffic offered from LEC to each IEC switch without considering network damage
	ACSlec_dam[MAX_SWITCH]	traffic offered from LEC to each IEC switch including effects of damage
	ACSiec[MAX_SWITCH]	traffic offered to IEC switch for inter-switch transport
	ACStest[MAX_SWITCH]	temporary testing of ACS
	PropIntra[MAX_SWITCH]	proportion of inter-switch traffic at each IEC switch
	D3[MAX_POP]	traffic offered from LEC to each POP
	D3live[MAX_POP]	traffic offered from LEC to each POP in the case of no network damage
	D3test[MAX_POP]	temporary testing of D3
	ACPiec[MAX_POP]	traffic through each POP engineered for inter-switch transport
	AC[MAX_EO]	traffic offered from each EO
	Lmult[MAX_LATA]	indicates regional overload multiplier for each LATA
	Rmult[MAX_REGION]	indicates regional overload multiplier assigned to each region
	ACSRegion[MAX_SWITCH][MAX_REGION]	indicates traffic offered to each switch from each region
	AvgSwRmult[MAX_SWITCH][MAX_REGION]	indicates the traffic-weighted average multiplier applied to each element of ACSRegion
	RmultMatrix[MAX_REGION][MAX_REGION]	indicates the traffic multiplier applied to traffic from one region to another
double	SS[MAX_SWITCH][MAX_SWITCH]	the main switch-to-switch proportions matrix that describes how traffic is distributed across the IEC backbone
	SSreg[MAX_SWITCH][MAX_SWITCH]	the SS matrix after being modified to reflect regional focused overload
	SSrow[MAX_SWITCH]	sum of an SS row, used for normalizing the matrix
	F0[MAX_EO][2]	Engineered access traffic at an EO divided by HU and final engineered proportions
	F0dmg[MAX_EO]	Engineered access traffic at an EO with damage considered
	RegF0dmg[MAX_EO]	Engineered access traffic at an EO with damage and regional overload considered

character	template[NUM_TEMP][15]	holds the labels for each section of the output file
	in_file[80]	name of network file output by attlive
	qlink_file[80]	name of qlink file
	eodmg_file[80]	name of EO damage file
	atdmg_file[80]	name of AT damage file
	popdmg_file[80]	name of POP damage file
	swdmg_file[80]	name of IEC switch damage file
	eoatdmg_file[80]	name of EO-AT span damage file
	eopopdmg_file[80]	name of EO-POP high usage span damage file
	atpopdmg_file[80]	name of AT-POP span damage file
	popswdmg_file[80]	name of POP-switch span damage file
	regovl_file[80]	name of regional overload file, if used

Local

Variables

Variables local to main() :

extern	integer	optind, argc	command line options counters
	character	*optarg, ** argv[]	reference to command line option string

character	c	general single character variable
	out_file[80]	name of output file
	keyfile[80]	name of keyfile
	line[200]	buffer for line of input from file
	temp[5]	temporary text buffer

integer	err	toggle to indicate error in command line arguments
	etog	toggle to indicate -e option
	stog	toggle to indicate -s option
	ttog	toggle to indicate -t option
	itog	toggle to indicate -i option
	otog	toggle to indicate -o option
	qtog	toggle to indicate -q option
	dtog	toggle to indicate -d option
	btog	toggle to indicate -b option
	stream	random number stream (default = 10)
	dvector	damage vector number to use (default = 1)
	early	indicates Early 1 or 2 cases (default = 0)
	done	used as a boolean in loops
	num_dead, num_tot	counts node and span damage summary statistics
	cap_live, cap_tot, cap	counts IEC TG damage summary statistics
	i, j, k, l, pm, p, m, n	general loop count variables
	test, surv, dummy	general temporary variables

float	sum_traf, sum_reg_traf	variables to count total traffic in the network
-------	------------------------	---

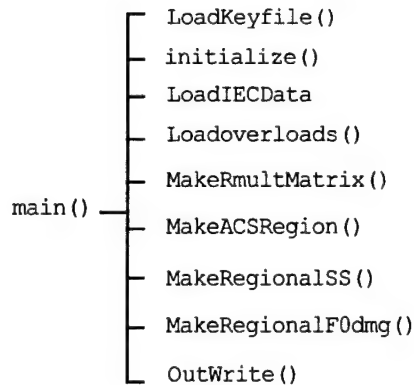

Component

Functions

LoadKeyfile()	Loads AT&T input file list from Keyfile
initialize()	Initializes all network and traffic variables
LoadIECData()	Loads input network file (output from attlive)
Loadoverloads()	Loads regional overload input file
MakeRmultMatrix()	Calculates the RmultMatrix structure
MakeACSRegion()	Calculates the ACSRegion value

MakeRegionalSS()	Calculates the backbone distribution matrix for regional overload
MakeRegionalF0dmg()	Calculates the EO access traffic for regional overload
OutWrite()	Writes network and traffic variables to output file

Function Tree

Algorithmic Description

Introduction—inputs and options: Module `attwdmg` is used to apply a given damage scenario to the undamaged AT&T network description and traffic matrix. It takes as input the undamaged AT&T network description and traffic matrix calculated by `attlive`. In addition, it requires a number of input damage files for each type of node and link (e.g., EO damage file, AT damage file, IEC switch damage file, etc.). Each damage file contains multiple damage scenarios, or vectors. The `tami` module passes the damage vector to be used when it invokes the `attwdmg` module in the `-d` option. Refer to Section 2 to identify the context of `attwdmg` within the overall TAMI data flow.

`Attwdmg` offers the choice of two sets of assumptions to create a post-damage traffic matrix, as specified by the `-e` option. The “early” assumption assumes that calls are attempted to both connected and unconnected destinations. The “late” assumption assumes that sufficient time has elapsed for users to learn which destinations are unreachable and to stop attempting to call these destinations; calls are only placed to connected destinations.

In addition to assessing the AT&T network and traffic matrix for damage, `attwdmg` can be used to create a regional focused overload traffic matrix if the `-r` option supplies a regional overload file. This input file is used to define a region as a set of LATAs and to describe the overload multiplier that should be used for traffic within the region, traffic leaving the region, and traffic entering the region. Up to five regions may be defined.

Output—`Attwdmg` creates a single, multi-section output file, usually called `att2lecam.out`, describing the damaged AT&T network, the post-damage traffic matrix, and a focused overload traffic matrix. This file is combined by the `merge` module with the output files for other IECs being analyzed before being passed to the `lecam` module for analysis.

Algorithm—The operation of `attwdmg` is described by the following five stages:

Stage 1: Process arguments, initialize, and load input files.

- 1.1 Command line arguments are read in and processed for legal combinations
- 1.2 The keyfile, a mandatory option, is opened and processed with a call to `LoadKeyfile()`

- 1.3 All global variables are initialized with a call to `initialize()`
- 1.4 Live network data (the output from `attlive`) is read in using a call to `LoadIECData()`.
- 1.5 If a regional overload is being performed (`-r` option), then the regional overload file is read in. This file describes the LATAs that comprise a region and the overloads that should be used into, out of, and within the region. `MakeRmultMatrix()` is called to make a region-to-region traffic multiplier matrix.
- 1.6 Damage vectors are read in one type at a time for all node and (optional) span damage types. Note that the damage vectors in the `qlink` file reflect pre-assessed damage results for switch-to-switch transmission paths in the IEC backbone. Therefore, individual backbone spans do not need to be considered in `attwdmg`

Stage 2: Assess affect of damage in access region

- 2.1 The first step is to damage EO-POP spans if they are not physically diverse from the AT, and the path through the AT is damaged. This only applies to type 3 EOs.
- 2.2 Next, damage is assessed by following homing chains up from an EO depending on the EO type:
 - 2.2.1 For type 1 EOs (HU-only homing), if any link along the HU homing fails, then traffic (`AC[k]`) cannot make it up that link from the EO. All affected variables are updated to reflect this. In the Early case, EO access traffic is only set to 0 (`AC=0`) if the EO itself is damaged. If not, the EO will offer traffic, but it will not be able to make it up the homing chain. In the Late case, an EO will not offer traffic if it is disconnected from the network in any way.
 - 2.2.2 For type 2 EOs (AT-only homing), if any link along the AT homing fails, then traffic will not make it up that homing from the EO. All affected variables are updated to reflect this depending on where the damage occurred along the homing. For the Early case, `AC=0` only if the EO itself is damaged. For the Late case, `AC=0` if there is any damage along the homing chain.
 - 2.2.3 For type 3 EOs (HU homing with overflow through an AT homing), both homings must fail to block EO access traffic from arriving at the POP and switch. If only the final homing fails, then all traffic is offered along the HU homing. If only the HU homing fails, then all traffic is offered along the final (AT) homing. In all cases, damage along either or both homing chains is reflected by updating appropriate trunk and traffic variables. As before, the distinction is drawn between the Early and Late cases.

Stage 3: Propagate affect of damage to egress region

In stage 2, access traffic was reduced at various points between the access EO and the access IEC switch due to damage in the access region. Stage 3 propagates this access traffic through the IEC backbone, building the switch-to-switch proportions matrix. An important observation for the Late case is that calls are not attempted to unconnected destinations. Therefore access traffic at each switch must be further reduced by the traffic-weighted proportion of destinations that are unreachable.

- 3.1 The switch-to-switch backbone distribution matrix, `SS`, is calculated in this step for inter-switch traffic. For AT&T, traffic is distributed from switch I to each switch J in proportion to the size of the trunk group from I to J. If the Late case is being calculated, then the calculation also reduces access traffic by each destination switch's proportion of unconnected EOs. For the Early case, traffic is allocated as if a normal connection existed to each destination.

- 3.2 Diagonal elements of SS represent intra-switch traffic proportions (e.g., the proportion of switch I's traffic that comes right back down to switch I). These quantities are calculated by multiplying the access traffic at a switch by PropIntra. As in 3.1, the Late case also involves reducing traffic in proportion to unreachable destinations.
- 3.3 At this point in the calculation, SS elements represent actual traffic values, not just proportions. The sum of each row of the SS matrix therefore represents the new access traffic for each switch, which would only be reduced from the original ACSlec if the Late case is being calculated. Each row of the SS matrix is set to this new access traffic value, ACSlec_dam.
- 3.4 To this point, the reduction in a switch's access traffic from ACSlec to ACSlec_dam has not been rolled all the way down to EO access traffic. In this step, the value F0dmg is set equal to AC for every EO, adjusted by the reduction from ACSlec to ACSlec_dam.

Stage 4: Calculate Effects of Regional Focused Overload

This stage calculates the network values that must change to reflect a regional focused overload, only in the event that `rtog` is true (indicating use of the `-r` option with a valid regional overload input file). There are three steps to this process.

- 4.1 The first step required is a call to `MakeACSRegion()` to calculate the `ACSRegion` array. This structure divides access traffic at each switch, `ACSlec_dam`, by region of origin. For example, if a switch serves EOs that are in two different regions, `ACSRegion` will hold the switch's access traffic from each region. This is required because the regional overload multiplier is in part a function of originating region.
- 4.2 The second step is a call to `MakeRegionalSS()` to calculate `SSReg`, the regional backbone traffic distribution. This step applies an overload from `RMultMatrix` to each normal SS element based on both origination and destination regions. `ACSRegion` is used from the previous step to perform traffic weighting. Note that this step does more than merely reportion traffic—it increases it based on focused overload affects among regions.
- 4.3 The last step is a call to `MakeRegionalF0dmg()` to ensure that the overloads in the `SSReg` matrix get reflected back down to the EOs that originate the traffic. This will inflate access traffic at each EO based on average focused overload affects from the EO to every other destination in the network. The result is placed in `RegF0dmg`. The end-to-end traffic for any pair of end offices can now be calculated using a combination of `RegF0dmg` and `SSReg`.

Stage 5: Write output file

This stage involves calling `OutWrite` to write each of the 25 network description data structures to the multi-section output file. This file will be processed by `merge` before being used by `lecam`.

Inputs

character keyfile[] string containing the name of the key file

Outputs

global	character[80]	eodmg_file	the name of the EO damage file
		atdmg_file	the name of the AT damage file
		eoatdmg_file	the name of the EO-AT span damage file
		regovl_file	the name of the regional overload file
		in_file	the name of the input network description created by attlive
		swdmg_file	the name of the IEC switch damage file
		popdmg_file	the name of the IEC POP damage file
		eopopdmg_file	the name of the EO-POP span damage file
		atpopdmg_file	the name of the AT-POP span damage file
		popswdmg_file	the name of the POP-switch span damage file
		qlink_file	the name of the qlink file

returns no formal values are returned

Purpose To read in the names of all necessary input files used by the main module

Called By main()

Calls To none

Local Variables

character	line[80]	temporarily holds a line of input from the keyfile
integer	att, mci spr	toggles used to indicate the presence of each IEC's data files in the keyfile

Global Variables

see Outputs above for others

file	* fptr	general file pointer variable used to open keyfile
------	--------	--

Algorithmic Description

This function opens and processes the TAMI keyfile, which contains the list of all input files required to perform a TAMI run. Refer to Appendix B (TAMI Keyfile description) for more detail on the keyfile.

LoadKeyfile processes the TAMI keyfile using the following four steps:

1. Skip past comment lines (lines starting with '#')
2. Process IEC string ('ATT/MCI/SPR') to make sure AT&T is included
3. Skip to LEC file section and read LEC damage file names
4. Skip to ATT section and read ATT file names

3-96

Inputs

file *inptr pointer to input IEC network file

Outputs Global network and traffic variables—described below under Algorithmic Description

returns no formal values are returned

Purpose To read in the undamaged network and traffic variables from the attlive output file

Called By main()

Calls To none

Local Variables

integer i, j, k, m, n, L, P, S loop variables
offset, count record position and counting variables

character line[100], temp[15] buffer memory

Global Variables

Global network and traffic variables—described below under Algorithmic Description.

character template[NUM_TEMP][15]

constant NUM_TEMP

Algorithmic Description

This function opens the undamaged network description created by attlive. It reads in each section of the file, as indicated by the section labels in the template[] array. The following global variables are loaded from the input file:

NUMSW	AC
NUMPOP	ACSlec / ACSlec_live
NUMAT	TAP
NUMEO	SAP
ATPOPSIZE	D3 / D3live
AT	ACPiec
HUPOP	popswitch
ATPOP	LATA
HAP	PhysDiv
SEP	IMT2
TEP	PropIntra
TEA	
F0	

Note that each of the 25 sections in the file may be stored in a different format and may have a different number of records depending on the variable type being read. For this reason, each section must be read in using the same formats used in attlive when the file was written out. The dimensions, NUMSW, NUMPOP, NUMAT, NUMEO, and ATPOPSIZE, are also used to determine the sizes of the sections that follow.

Inputs

character *infile input file

Outputs

returns no formal returns

Globals:

float	Rmult	regional traffic multiplier
	Lmult	LATA traffic multiplier
integer	LReg	LATA to region mapping
	EOReg	EO to region mapping

Purpose This routine loads regional information.

Called By main()

Calls To library functions
 print_info(void)

Local Variables

double	multiplier	
character	buffer1[80] , buffer2[80]	
		working memory
integer	i, lata, region	loop variable
FILE	*inputfile	input file

Global Variables

integer	NUMREGIONS
	NUMEO
	EOLata
	EO_SIZE

Algorithmic Description

Loadoverloads() first opens the indicated file. For each region, it then retrieves the region designation and multiplier. It then reads one line for each LATA in the region. The overload and region designation for the lata is then set. Loadoverloads() then closes the file, and sets the region for each EO.

Inputs none

Outputs

returns no formal returns

Globals:

float RmultMatrix

Purpose This routine generates a matrix of region to region traffic multipliers.

Called By main()

Calls To library functions

**Local
Variables**

integer i, j loop variable

**Global
Variables**

float Rmult

**Algorithmic
Description**

This routine builds a symmetric region to region traffic multiplier matrix. The region to region traffic multiplier is taken as the max of the two regional multipliers.

Inputs	none	
Outputs		
global	float	ACSRegion[NUM_SWITCH][NUM_REGION]
returns	no formal values are returned	
Purpose	To categorize switch access traffic by region of origin for a regional focused overload run	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable
Global Variables		
integer	EOReg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	post-damage engineered access traffic at an EO
Algorithmic Description	This function sums up F0dmg for each EO to its home switch based on the region, EOReg, in which the EO is located. Its purpose is to aggregate and track, at the IEC switch level, the originating region of all access traffic. This result is important for calculating the regional SS matrix in function MakeRegionalSS().	

Inputs	none	
Outputs		
global	float	AvgSwRmult[NUM_SWITCH] [NUM_REGION]
	float	SSreg[NUM_SWITCH] [NUM_SWITCH]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	i, j	loop variables on dimension NUMSW
	Ri, Rj	loop variables on dimension NUMREGION
Global Variables		
integer	EOREg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	ACSlec_dam	for every switch, indicates post-damage access traffic before regional overload is assessed
	RmultMatrix	regional overload affect for every pair of originating and terminating regions
	ACSRegion	access traffic offered from each region through each switch
	SS	non-regional backbone traffic distribution
Algorithmic Description	<p>This function calculates the regional focused overload affect for each switch pair and stores the result in SSreg. For every switch pair, traffic is examined for every possible pair of regions between the switches. Each element of this traffic is subjected to overload defined by RmultMatrix. For example, from region Ri at switch i, to region Rj at switch j, traffic is overloaded by RmultMatrix[Ri] [Rj] . These elements are weighted base on traffic at both ends, summed for all region combinations, and normalized to determine the average overload between the switch pair. This quantity, SStemp/ACSlec_dam, is multiplied by the original SS value to yield a regional overloaded SSreg value.</p> <p>Note that an important intermediate result, AvgSwRmult, is calculated along the way. This value is the average focused-overload-induced multiplier applied to traffic leaving region Ri through switch i. It is computed from the overload experienced from region Ri at switch i to every other region/switch combination, Rj and j. This result has intentionally not been weighted by access traffic. This allows it to be used on a case-by-case basis for various access traffic values, as seen in function MakeRegionalF0dmg() .</p>	

Inputs	none	
Outputs		
global	float	RegF0dmg[NUM_EO]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable on dimension NUMEO
Global Variables		
integer	E0Reg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	for every EO, indicates the engineered access traffic prior to regional focused overload affects
	AvgSwRmult	indicates the traffic-weighted average regional focused overload experienced by access traffic from each region through each switch
Algorithmic Description	This function calculates RegF0dmg for every EO. This quantity is a function of the post-damage engineered access traffic at the EO, F0dmg, and the average overload caused by regional overload effects, AvgSwRmult. AvgSwRmult, in turn, is a function of what region the EO resides in, and what switch it is homed to. For a regional focused overload, RegF0dmg represents the load offered at the EOs to the IEC.	

Inputs	
file	*outptr pointer to output damaged IEC network file
Outputs Global network and traffic variables are written to file—described below under Algorithmic Description	
returns	no formal values are returned
Purpose	To write out all the damaged network and traffic variables to the output file
Called By	main()
Calls To	none
Local Variables	
integer	k, l, m, n loop variables
Global Variables Global network and traffic variables—described below under Algorithmic Description.	
Algorithmic Description This function writes a carrier-specific header to the output file, followed by the global damaged network and traffic variables. Each variable is written to a labeled section, with the following description:	
IECid	identifies the carrier (att, mci, or spr)
SWITCH_SIZE	number of IEC switches in the network
POP_SIZE	number of POPs in the network
AT_SIZE	number of ATs in the network
EO_SIZE	number of EOs in the network
ATPOPSIZE	maximum number of POPs an AT homes to for this network
EOAT	for every EO, identifies the homed AT (-1 if N/A)
HUPOP	for every EO, identifies the homed HU POP
ATPOP	for every EO, identifies the homed POP through the AT
HAP	for every AT, identifies all homed POPs
SD	for every EO, identifies the size of the EO-POP TG
TEA	for every EO, identifies the total (both ways) traffic engineered for the EO-AT TG
F0	for every EO, identifies the components of access traffic offered to the HU and final homings respectively
F0dmg	for every EO, identifies the amount of engineered access traffic offered by the EO after damage affects are considered
ELAP	for every AT, identifies the total AT-POP traffic for each AT-POP homing defined in HAP
SAP	for every AT, identifies the size of each AT-POP TG
ACS	for every IEC switch, identifies the total access traffic offered for inter-switch transport
POPSWITCH	for every POP, identifies the homed IEC switch
AC1	for every EO, identifies the actual traffic offered, including regional focused overload, if applicable

EOalive	for every EO, indicates 0/1 for failure/survival
ATalive	for every AT, indicates 0/1 for failure/survival
POPalive	for every POP, indicates 0/1 for failure/survival
SWalive	for every switch, indicates 0/1 for failure/survival
EOLata	for every EO, identifies its LATA
PhysDiv	for every EO, identifies if the HU homing (if any) is physically diverse from the final homing (if any)
SS	for the matrix of IEC switch pairs, identifies traffic distribution from one switch to the other
SSreg	same as SS, but for regional focused overload
PropIntra	for every switch, indicates the proportion of access traffic that is intra-switch traffic

Note that each of the sections in the file may be stored in a different format and may have a different number of records depending on the variable type being written.

3.8 mciwdmg: Pre-process Damaged MCI Network and Traffic

Purpose This module performs the data preparation calculations required to assess the affects of damage to the LEC homing chains and end-to-end traffic matrix for the MCI network. Many of the engineered traffic variables computed by `mcilive` are adjusted to reflect post-damage engineered traffic under Early and Late scenarios. For a regional analysis, this module computes the focused overload offered load matrix through MCI. The output file from this module is merged with the other IEC files in the `merge` module before being input into the `lecam` module.

Call Syntax `mciwdmg -k <key file> [options]`

mandatory:

- d use damage vector <number> for this run
- k reads in input file <key file>

options:

- b blast-type damage: use physical diversity model for HU damage
- e specify early scenario <1> or <2>
- i no longer used
- r reads in regional overload input file <reg file>
- s specify non-default random number generator stream using <stream> from 1 to 15
- ? user help—prints call syntax and exits without running

example `mciwdmg -k tamirun.key -d5`

Input Files

The list of input files required by `mciwdmg` is supplied in the keyfile. See Appendix B for these files.

reg file In addition to the files in the keyfile, for a regional overload run, the `-r` option will specify a regional overload file, <reg file>. The first line of this file specifies the default (Region 0) overload. Unless specified in later regions, all LATAs will be overloaded based on this default. The second line defines Region 1 and its overload value. The next line contains a list of space-separated LATA numbers that are members of Region 1. Subsequent regions are defined similarly, up to a maximum of five regions.

format

<code>R0, <region overload></code>	default region line
<code><Region number>, <region overload></code>	subsequent region line
<code>(c2, 1x, f)</code>	
<code><LATA number>, . . . , <LATA number></code>	with associated LATAs
<code>(i3, 1x, . . . , i3, 1x, i3)</code>	

example

<code>R0 1.25</code>	defines 1.25 overload for default LATAs
<code>R1 5.0</code>	defines 5.0 overload for region 1 LATAs
<code>132 133 134</code>	region 1 LATAs defined here as a list
<code>R2 10.0</code>	defines 10.0 overload for region 2 LATAs
<code>251 291 237 252</code>	region 2 LATAs defined here as a list

ppmeanfile Additionally, `mciwdmg` reads in a file with the hardcoded name "ppmeanfile.mci." This file contains a matrix of switch to switch blockages for MCI which indicate whether a connection exists between two switches given the routing rules and damage scenario. This file is created

by `qmod_mci`. Each line contains 12 row elements of the switch-to-switch blockage matrix, and the row will wrap as many lines as necessary. If a row ends midway through a line, the rest of that line is blank. The next row of the matrix will begin on a new line until the entire matrix has been printed. Elements are separated by spaces within a line.

Output

Files `mci2lecam.out`--multisection output file described in function `Outwrite`

Includes `"fileio.c"` includes input/output utility functions—see Appendix A
`"lecam.h"` defines lecam constants and variables—see Section 3.11
`"waglib.h"` defines random number generator functions, constants, and data structures—not used

Constants `MAX_BIN 3` Not used
`NUM_TEMP 25` Number of sections in output file

constants defined in `lecam.h` (network sizing variables) and used in `mciwdmg`:

<code>TRUE</code>	1	
<code>FALSE</code>	0	
<code>MAX_AT</code>	1000	Maximum number of ATs in network
<code>MAX_EO</code>	19250	Maximum number of EOs in network
<code>ATPOPMAX</code>	9	Maximum number of POPs a single AT may home to
<code>MAX_POP</code>	575	Maximum number of POPs in network
<code>MAX_SWITCH</code>	130	Maximum number of IEC switches in network
<code>MAX_LATA</code>	1000	Maximum number of LATAs
<code>MAX_REGION</code>	5	Maximum number of regions defined for regional overload

Global Variables

FILE	<code>* inptr</code>	File pointer for an input file
	<code>* outptr</code>	File pointer for the output file
	<code>* fptr</code>	File pointer for any file
int	<code>KEYTOG</code>	toggle for -k option
	<code>rtog</code>	toggle for -r option
	<code>NUMEO</code>	number of EOs in network
	<code>NUMAT</code>	number of ATs in network
	<code>NUMPOP</code>	number of POPs in network
	<code>NUMSW</code>	number of backbone switches in network
	<code>NUMREGIONS</code>	number of regions defined for regional overload
	<code>ATPOPSIZE</code>	maximum number of AT-POP homing segments
	<code>HAP[MAX_AT][ATPOPMAX]</code>	AT-POP homings
	<code>AT[MAX_EO]</code>	homed AT for an EO
	<code>ATPOP[MAX_EO]</code>	homed POP through the AT for an EO
	<code>HUPOP[MAX_EO]</code>	homed high-usage POP for an EO
	<code>SW[MAX_EO]</code>	homed IEC switch for an EO
	<code>TYPE[MAX_EO]</code>	homing type for an EO
	<code>LATA[MAX_EO]</code>	LATA designation for an EO
	<code>popswitch[MAX_POP]</code>	homed IEC switch for POP
	<code>IMT[MAX_SWITCH][MAX_SWITCH]</code>	matrix of IMT TGs between IEC switches
	<code>IMT2[MAX_SWITCH][MAX_SWITCH]</code>	copy of IMT matrix used for data checking purposes

	IMTdam[MAX_SWITCH] [MAX_SWITCH]	damaged IMT matrix
	SUM_IMT[MAX_SWITCH]	total IMT TGs originating or terminating at each IEC switch
	SAP[MAX_AT] [ATPOPMAX]	size of AT-POP TG for each POP homed to AT
	SEP[MAX_EO]	size of the direct EO-POP TG, if exists
	PhysDiv[MAX_EO]	0/1 indication of whether the HU TG, if existing, is physically diverse from the AT
	EOalive[MAX_EO]	0/1 indication of survival of EO
	ATalive[MAX_AT]	0/1 indication of survival of AT
	POPalive[MAX_POP]	0/1 indication of survival of POP
	SWalive[MAX_SW]	0/1 indication of survival of IEC switch
	EOATalive[MAX_EO]	0/1 indication of survival of EO-AT span
	ATPOPalive[MAX_AT] [ATPOPMAX]	0/1 indication of survival of AT-POP span
	EOPOPalive[MAX_EO]	0/1 indication of survival of EO-POP span
	POPSwalive[MAX_POP]	0/1 indication of survival of POP-SW span
	LReg[MAX_LATA]	Indicates which Region each LATA is in
	EOREg[MAX_EO]	Indicates which Region each EO is in
float	TAP[MAX_AT] [ATPOPMAX]	traffic engineered for SAP TGs
	TEP[MAX_EO]	traffic engineered for SEP TGs
	TEA[MAX_EO]	traffic engineered between EO and AT
	ACSlec[MAX_SWITCH]	traffic offered from LEC to each IEC switch
	ACSlec_live[MAX_SWITCH]	traffic offered from LEC to each IEC switch without considering network damage
	ACSlec_dam[MAX_SWITCH]	traffic offered from LEC to each IEC switch including effects of damage
	ACSiec[MAX_SWITCH]	traffic offered to IEC switch for inter-switch transport
	ACStest[MAX_SWITCH]	temporary testing of ACS
	PropIntra[MAX_SWITCH]	proportion of inter-switch traffic at each IEC switch
	D3[MAX_POP]	traffic offered from LEC to each POP
	D3live[MAX_POP]	traffic offered from LEC to each POP in the case of no network damage
	D3test[MAX_POP]	temporary testing of D3
	ACPiec[MAX_POP]	traffic through each POP engineered for inter-switch transport
	AC[MAX_EO]	traffic offered from each EO
	Morph[MAX_SWITCH] [MAX_SWITCH] , MorphRow[MAX_SWITCH]	holds the proportions matrix elements, and a row sum respectively, read in from the traffic distribution input file
	SWBLOCK[MAX_SWITCH] [MAX_SWITCH]	holds the switch-to-switch connectivity results read in from ppmeanfile.mci
	Lmult[MAX_LATA]	indicates regional overload multiplier for each LATA
	Rmult[MAX_REGION]	indicates regional overload multiplier assigned to each region
	ACSRegion[MAX_SWITCH] [MAX_REGION]	indicates traffic offered to each switch from each region
	AvgSwRmult[MAX_SWITCH] [MAX_REGION]	indicates the traffic-weighted average multiplier applied to each element of ACSRegion

	RmultMatrix[MAX_REGION][MAX_REGION]	indicates the traffic multiplier applied to traffic from one region to another
double	SS[MAX_SWITCH][MAX_SWITCH]	the main switch-to-switch proportions matrix that describes how traffic is distributed across the IEC backbone
	SSreg[MAX_SWITCH][MAX_SWITCH]	the SS matrix after being modified to reflect regional focused overload
	SSrow[MAX_SWITCH]	sum of an SS row, used for normalizing the matrix
	F0[MAX_EO][2]	Engineered access traffic at an EO divided by HU and final engineered proportions
	F0dmg[MAX_EO]	Engineered access traffic at an EO with damage considered
	RegF0dmg[MAX_EO]	Engineered access traffic at an EO with damage and regional overload considered
character	template[NUM_TEMP][15]	holds the labels for each section of the output file
	in_file[80]	name of network file output by mcilive
	qlink_file[80]	name of qlink file
	morph_file[80]	name of traffic distribution file
	eodmg_file[80]	name of EO damage file
	atdmg_file[80]	name of AT damage file
	popdmg_file[80]	name of POP damage file
	swdmg_file[80]	name of IEC switch damage file
	eoatdmg_file[80]	name of EO-AT span damage file
	eopopdmg_file[80]	name of EO-POP high usage span damage file
	atpopdmg_file[80]	name of AT-POP span damage file
	popswdmg_file[80]	name of POP-switch span damage file
	regovl_file[80]	name of regional overload file, if used

Local Variables

	Variables local to main() :	
extern	integer optind, argc	command line options counters
	character *optarg,**argv[]	reference to command line option string
char	c	general single character variable
	out_file[80]	name of output file
	keyfile[80]	name of keyfile
	line[200]	buffer for line of input from file
	temp[5]	temporary text buffer
int	err	toggle to indicate error in command line arguments
	etog	toggle to indicate -e option
	stog	toggle to indicate -s option
	ttog	toggle to indicate -t option
	itog	toggle to indicate -i option
	otog	toggle to indicate -o option
	qtog	toggle to indicate -q option
	dtog	toggle to indicate -d option
	btog	toggle to indicate -b option
	stream	random number stream (default = 10)

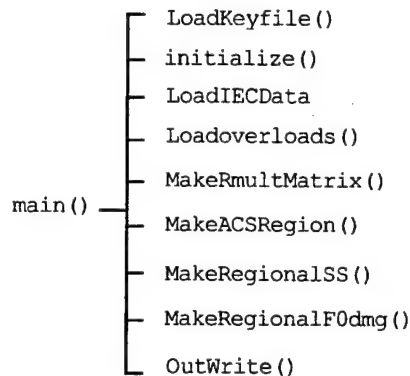

dvector	damage vector number to use (default = 1)
early	indicates Early 1 or 2 cases (default = 0)
done	used as a boolean in loops
num_dead, num_tot	counts node and span damage summary statistics
cap_live, cap_tot, cap	counts IEC TG damage summary statistics
i, j, k, l, pm, p, m, n	general loop count variables
test, surv, dummy	general temporary variables

float sum_traf, sum_reg_traf variables to count total traffic in the network

Component Functions

LoadKeyfile()	Loads AT&T input file list from Keyfile
initialize()	Initializes all network and traffic variables
LoadIECData()	Loads input network file (output from mcilive)
Loadoverloads()	Loads regional overload input file
MakeRmultMatrix()	Calculates the RmultMatrix structure
MakeACSRegion()	Calculates the ACSRegion value
MakeRegionalSS()	Calculates the backbone distribution matrix for regional overload
MakeRegionalF0dmg()	Calculates the EO access traffic for regional overload
OutWrite()	Writes network and traffic variables to output file

Function Tree

Algorithmic Description

Module mciwdmg is used to apply a given damage scenario to the undamaged MCI network description and traffic matrix. In almost every aspect, it is the same as the attwdmg module. The differences from attwdmg are described here, referencing the attwdmg module documentation where appropriate.

For attwdmg, it was assumed that backbone traffic was distributed in proportion to the trunks. In MCI, this assumption does not hold. Therefore, mciwdmg requires an additional input file, which the mciwdmg code refers to as the morph file, to describe the undamaged traffic distribution. Refer to mcilive module documentation for more information on the calculation of this traffic distribution file.

In addition, mciwdmg requires the determination of connectivity between a pair of backbone switches. For AT&T and Sprint, which are assumed to have direct trunking between all switch pairs, the IMTdam parameter was sufficient. For MCI, which uses hierarchical routing, this parameter cannot be used. Instead, a "trickle current" qtc module run is performed. This run uses the minimum allowed offered traffic matrix between switches so as not to cause blocking due to congestion. If there is no route for traffic between two switches, the blocking will still

show up as 1.0, indicating no connectivity. This information is read in to the `SWBLOCK[i][j]` variable from the `ppmeanfile.mci` file output by `qtcn`.

Both the `morph` file and `ppmeanfile.mci` are applied in the calculation of `SS`. Where `attwdmg` uses `IMT[i][j] / SUM_IMT[i]` to distribute switch `i`'s traffic to all other switches `j`, `mciwdmg` replaces this term with `Morph[i][j] / MorphRow[i]`. In addition, code supporting the `SS` calculation uses the term `MorphRow[i]` instead of the term `SUM_IMT[i]`. The `ppmeanfile` information is used for the Late case calculation of `SS`, where it must be determined whether a connection exists between a pair of switches. The calculation for `mciwdmg` replaces the term `IMTdam[i] == 0` with the term `SWBLOCK[i] == 1.0` in the "if" clause that determines connectivity between switches.

In all other respects, `mciwdmg` operates identically to `attwdmg`.

Inputs

character keyfile[] string containing the name of the key file

Outputs

global	character[80]	eodmg_file	the name of the EO damage file
		atdmg_file	the name of the AT damage file
		eoatdmg_file	the name of the EO-AT span damage file
		regovl_file	the name of the regional overload file
		in_file	the name of the input network description created by attlive
		swdmg_file	the name of the IEC switch damage file
		popdmg_file	the name of the IEC POP damage file
		eopopdmg_file	the name of the EO-POP span damage file
		atpopdmg_file	the name of the AT-POP span damage file
		popswdmg_file	the name of the POP-switch span damage file
		qlink_file	the name of the qlink file
		morph_file	the name of the IEC traffic distribution file

returns no formal values are returned

Purpose To read in the names of all necessary input files used by the main module

Called By main()

Calls To none

Local Variables

character	line[80]	temporarily holds a line of input from the keyfile
integer	att, mci spr	toggles used to indicate the presence of each IEC's data files in the keyfile

Global Variables

see Outputs above for others

file	*fptr	general file pointer variable used to open keyfile
------	-------	--

Algorithmic Description

This function opens and processes the TAMI keyfile, which contains the list of all input files required to perform a TAMI run. Refer to Appendix B (TAMI Keyfile description) for more detail on the keyfile.

LoadKeyfile processes the TAMI keyfile using the following four steps:

1. Skip past comment lines (lines starting with '#')
2. Process IEC string ('ATT/MCI/SPR') to make sure MCI is included
3. Skip to LEC file section and read LEC damage file names
4. Skip to MCI section and read MCI input file names

Inputs none

Outputs none

returns no formal values are returned

Purpose To initialize all of the network and traffic variables before they are read in from the input files

Called By `main()`

Calls To none

**Local
Variables**

integer `i, j` loop variables

**Global
Variables** All global network and traffic variables. See main module description.

**Algorithmic
Description** This function initializes all network and traffic variables. Traffic and trunk size quantities are initialized to 0. Damage vectors are initialized to 1 (survival). `Popswitch[]` is initialized to -1 to indicate no switch homed to each POP.

Inputs

file *inptr pointer to input IEC network file

Outputs Global network and traffic variables—described below under Algorithmic Description

returns no formal values are returned

Purpose To read in the undamaged network and traffic variables from the mcilive output file

Called By main()

Calls To none

Local Variables

integer	i, j, k, m, n, L, P, S	loop variables
	offset, count	record position and counting variables
character	line[100], temp[15]	buffer memory

Global Variables

Global network and traffic variables—described below under Algorithmic Description.

char	template[NUM_TEMP][15]
constant	NUM_TEMP

Algorithmic Description

This function opens the undamaged network description created by mcilive. It reads in each section of the file, as indicated by the section labels in the template[] array. The following global variables are loaded from the input file:

NUMSW	AC
NUMPOP	ACSlec / ACSlec_live
NUMAT	TAP
NUMEO	SAP
ATPOPSIZE	D3 / D3live
AT	ACPiec
HUPOP	popswitch
ATPOP	LATA
HAP	PhysDiv
SEP	IMT2
TEP	PropIntra
TEA	
F0	

Note that each of the 25 sections in the file may be stored in a different format and may have a different number of records depending on the variable type being read. For this reason, each section must be read in using the same formats used in mcilive when the file was written out. The dimensions, NUMSW, NUMPOP, NUMAT, NUMEO, and ATPOPSIZE, are also used to determine the sizes of the sections that follow.

Inputs

character *infile input file

Outputs

returns no formal returns

Globals:

real	Rmult	regional traffic multiplier
	Lmult	LATA traffic multiplier
integer	LReg	LATA to region mapping
	EOReg	EO to region mapping

Purpose This routine loads regional information.

Called By main()

Calls To library functions
print_info(void)

Local Variables

double	multiplier	
character	buffer1[80] , buffer2[80]	
		working memory
integer	i,lata, region	loop variable
FILE	*inputfile	input file

Global Variables

integer	NUMREGIONS
	NUMEO
	EOLata
	EO_SIZE

Algorithmic Description

Loadoverloads() first opens the indicated file. For each region, it then retrieves the region designation and multiplier. It then reads one line for each LATA in the region. The overload and region designation for the lata is then set. Loadoverloads() then closes the file, and sets the region for each EO.

3.8.5 MakeRmultMatrix function

mciwdmg module

Inputs none

Outputs

returns no formal returns

Globals:

```
real  RmultMatrix
```

Purpose

This routine generates a matrix of region to region traffic multipliers..

Called By

```
main()
```

Calls To

library functions

Local Variables

integer	i, j	loop variable
---------	------	---------------

Global Variables

```
real      Rmult
```

Algorithmic Description

This routine builds a symmetric region to region traffic multiplier matrix. The region to region traffic multiplier is taken as the max of the two regional multipliers.

Inputs	none	
Outputs		
global	float	ACSRegion[NUM_SWITCH][NUM_REGION]
returns	no formal values are returned	
Purpose	To categorize switch access traffic by region of origin for a regional focused overload run	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable
Global Variables		
integer	EOReg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	post-damage engineered access traffic at an EO
Algorithmic Description	This function sums up F0dmg for each EO to its home switch based on the region, EOReg, in which the EO is located. Its purpose is to aggregate and track, at the IEC switch level, the originating region of all access traffic. This result is important for calculating the regional SS matrix in function MakeRegionalSS().	

Inputs	none	
Outputs		
global	float	AvgSwRmult[NUM_SWITCH][NUM_REGION]
	float	SSreg[NUM_SWITCH][NUM_SWITCH]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	i, j	loop variables on dimension NUMSW
	Ri, Rj	loop variables on dimension NUMREGION
Global Variables		
int	EOREg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	ACSlec_dam	for every switch, indicates post-damage access traffic before regional overload is assessed
	RmultMatrix	regional overload affect for every pair of originating and terminating regions
	ACSRegion	access traffic offered from each region through each switch
	SS	non-regional backbone traffic distribution
Algorithmic Description	<p>This function calculates the regional focused overload affect for each switch pair and stores the result in SSreg. For every switch pair, traffic is examined for every possible pair of regions between the switches. Each element of this traffic is subjected to overload defined by RmultMatrix. For example, from region Ri at switch i, to region Rj at switch j, traffic is overloaded by RmultMatrix[Ri][Rj] . These elements are weighted base on traffic at both ends, summed for all region combinations, and normalized to determine the average overload between the switch pair. This quantity, SStemp/ACSlec_dam, is multiplied by the original SS value to yield a regional overloaded SSreg value.</p> <p>Note that an important intermediate result, AvgSwRmult, is calculated along the way. This value is the average focused-overload-induced multiplier applied to traffic leaving region Ri through switch i. It is computed from the overload experienced from region Ri at switch i to every other region/switch combination, Rj and j. This result has intentionally not been weighted by access traffic. This allows it to be used on a case-by-case basis for various access traffic values, as seen in function MakeRegionalF0dmg() .</p>	

Inputs	none	
Outputs		
global	float	RegF0dmg[NUM_EO]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable on dimension NUMEO
Global Variables		
int	E0Reg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	for every EO, indicates the engineered access traffic prior to regional focused overload affects
	AvgSwRmult	indicates the traffic-weighted average regional focused overload experienced by access traffic from each region through each switch
Algorithmic Description	This function calculates RegF0dmg for every EO. This quantity is a function of the post-damage engineered access traffic at the EO, F0dmg, and the average overload caused by regional overload effects, AvgSwRmult. AvgSwRmult, in turn, is a function of what region the EO resides in, and what switch it is homed to. For a regional focused overload, RegF0dmg represents the load offered at the EOs to the IEC.	

Inputs	
file	*outptr pointer to output damaged IEC network file
Outputs Global network and traffic variables are written to file—described below under Algorithmic Description	
returns	no formal values are returned
Purpose To write out all the damaged network and traffic variables to the output file	
Called By main()	
Calls To none	
Local Variables	
integer	k, l, m, n loop variables
Global Variables Global network and traffic variables—described below under Algorithmic Description.	
Algorithmic Description This function writes a carrier-specific header to the output file, followed by the global damaged network and traffic variables. Each variable is written to a labeled section, with the following description:	
IECid	identifies the carrier (att, mci, or spr)
SWITCH_SIZE	number of IEC switches in the network
POP_SIZE	number of POPs in the network
AT_SIZE	number of ATs in the network
EO_SIZE	number of EOs in the network
ATPOPSIZE	maximum number of POPs an AT homes to for this network
EOAT	for every EO, identifies the homed AT (-1 if N/A)
HUPOP	for every EO, identifies the homed HU POP
ATPOP	for every EO, identifies the homed POP through the AT
HAP	for every AT, identifies all homed POPs
SD	for every EO, identifies the size of the EO-POP TG
TEA	for every EO, identifies the total (both ways) traffic engineered for the EO-AT TG
F0	for every EO, identifies the components of access traffic offered to the HU and final homings respectively
F0dmg	for every EO, identifies the amount of engineered access traffic offered by the EO after damage affects are considered
ELAP	for every AT, identifies the total AT-POP traffic for each AT-POP homing defined in HAP
SAP	for every AT, identifies the size of each AT-POP TG
ACS	for every IEC switch, identifies the total access traffic offered for inter-switch transport
POPSWITCH	for every POP, identifies the homed IEC switch
AC1	for every EO, identifies the actual traffic offered, including regional focused overload, if applicable

EOalive	for every EO, indicates 0/1 for failure/survival
ATalive	for every AT, indicates 0/1 for failure/survival
POPalive	for every POP, indicates 0/1 for failure/survival
SWalive	for every switch, indicates 0/1 for failure/survival
EOLata	for every EO, identifies its LATA
PhysDiv	for every EO, identifies if the HU homing (if any) is physically diverse from the final homing (if any)
SS	for the matrix of IEC switch pairs, identifies traffic distribution from one switch to the other
SSreg	same as SS, but for regional focused overload
PropIntra	for every switch, indicates the proportion of access traffic that is intra-switch traffic

Note that each of the sections in the file may be stored in a different format and may have a different number of records depending on the variable type being written.

3.9 sprwdmg: Pre-process Damaged Sprint Network and Traffic

Purpose This module performs the data preparation calculations required to assess the affects of damage to the LEC homing chains and end-to-end traffic matrix for the Sprint network. Many of the engineered traffic variables computed by `sprlive` are adjusted to reflect post-damage engineered traffic under Early and Late scenarios. For a regional analysis, this module computes the focused overload offered load matrix through Sprint. The output file from this module is merged with the other IEC files in the `merge` module before being input into the `lecam` module.

Call Syntax `sprwdmg -k <key file> [options]`
mandatory:
 -d use damage vector <number> for this run
 -k reads in input file <key file>

options:
 -b blast-type damage: use physical diversity model for HU damage
 -e specify early scenario <1> or <2>
 -i no longer used
 -r reads in regional overload input file <reg file>
 -s specify non-default random number generator stream using <stream> from
 1 to 15
 -? user help—prints call syntax and exits without running

example `sprwdmg -k tamirun.key -d5`

**Input
Files**

The list of input files required by `sprwdmg` is supplied in the keyfile. See Appendix B (TAMI keyfile description) for these files.

reg file In addition to the files in the keyfile, for a regional overload run, the `-r` option will specify a regional overload file, <reg file>. The first line of this file specifies the default (Region 0) overload. Unless specified in later regions, all LATAs will be overloaded based on this default. The second line defines Region 1 and its overload value. The next line contains a list of space-separated LATA numbers that are members of Region 1. Subsequent regions are defined similarly, up to a maximum of five regions.

format R0, <region overload> default region line
 <Region number>, <region overload>
 subsequent region line

 (c2, 1x, f)

 <LATA number>, . . . , <LATA number>
 with associated LATAs

 (i3, 1x, . . . , i3, 1x, i3)

example R0 1.25 defines 1.25 overload for default LATAs
 R1 5.0 defines 5.0 overload for region 1 LATAs
 132 133 134 region 1 LATAs defined here as a list
 R2 10.0 defines 10.0 overload for region 2 LATAs
 251 291 237 252 region 2 LATAs defined here as a list

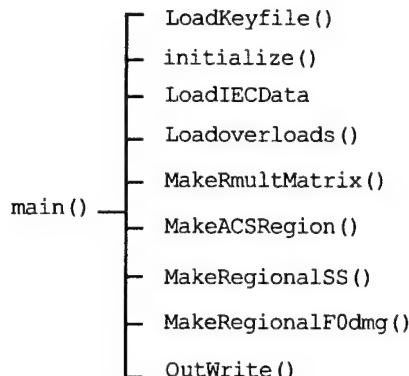

Output Files		spr2lecam.out—multisection output file described in function Outwrite
Includes	"fileio.c"	includes input/output utility functions—see Appendix A
	"lecam.h"	defines lecam constants and variables—see Section 3.11
	"waglib.h"	defines random number generator functions, constants, and data structures—not used
Constants	MAX_BIN 3	Not used
	NUM_TEMP 25	Number of sections in output file
constants defined in lecam.h (network sizing variables) and used in sprwdmg:		
	TRUE 1	
	FALSE 0	
	MAX_AT 1000	Maximum number of ATs in network
	MAX_EO 19250	Maximum number of EOs in network
	ATPOPMAX 9	Maximum number of POPs a single AT may home to
	MAX_POP 575	Maximum number of POPs in network
	MAX_SWITCH 130	Maximum number of IEC switches in network
	MAX_LATA 1000	Maximum number of LATAs
	MAX_REGION 5	Maximum number of regions defined for regional overload
Global Variables		
FILE	* inptr	File pointer for an input file
	* outptr	File pointer for the output file
	* fptr	File pointer for any file
integer	KEYTOG	toggle for -k option
	rtog	toggle for -r option
	NUMEO	number of EOs in network
	NUMAT	number of ATs in network
	NUMPOP	number of POPs in network
	NUMSW	number of backbone switches in network
	NUMREGIONS	number of regions defined for regional overload
	ATPOPSIZE	maximum number of AT-POP homing segments
	HAP[MAX_AT][ATPOPMAX]	AT-POP homings
	AT[MAX_EO]	homed AT for an EO
	ATPOP[MAX_EO]	homed POP through the AT for an EO
	HUPOP[MAX_EO]	homed high-usage POP for an EO
	SW[MAX_EO]	homed IEC switch for an EO
	TYPE[MAX_EO]	homing type for an EO
	LATA[MAX_EO]	LATA designation for an EO
	popswitch[MAX_POP]	homed IEC switch for POP
	IMT[MAX_SWITCH][MAX_SWITCH]	matrix of IMT TGs between IEC switches
	IMT2[MAX_SWITCH][MAX_SWITCH]	copy of IMT matrix used for data checking purposes
	IMTdam[MAX_SWITCH][MAX_SWITCH]	damaged IMT matrix
	SUM_IMT[MAX_SWITCH]	total IMT TGs originating or terminating at each IEC switch
	SAP[MAX_AT][ATPOPMAX]	size of AT-POP TG for each POP homed to AT

	SEP[MAX_EO]	size of the direct EO-POP TG, if exists
	PhysDiv[MAX_EO]	0/1 indication of whether the HU TG, if existing, is physically diverse from the AT
	EOalive[MAX_EO]	0/1 indication of survival of EO
	ATalive[MAX_AT]	0/1 indication of survival of AT
	POPalive[MAX_POP]	0/1 indication of survival of POP
	SWalive[MAX_SW]	0/1 indication of survival of IEC switch
	EOATalive[MAX_EO]	0/1 indication of survival of EO-AT span
	ATPOPalive[MAX_AT] [ATPOPMAX]	0/1 indication of survival of AT-POP span
	EOPOPalive[MAX_EO]	0/1 indication of survival of EO-POP span
	POPSWalive[MAX_POP]	0/1 indication of survival of POP-SW span
	LReg[MAX_LATA]	Indicates which Region each LATA is in
	EOREg[MAX_EO]	Indicates which Region each EO is in
float	TAP[MAX_AT] [ATPOPMAX]	traffic engineered for SAP TGs
	TEP[MAX_EO]	traffic engineered for SEP TGs
	TEA[MAX_EO]	traffic engineered between EO and AT
	ACSlec[MAX_SWITCH]	traffic offered from LEC to each IEC switch
	ACSlec_live[MAX_SWITCH]	traffic offered from LEC to each IEC switch without considering network damage
	ACSlec_dam[MAX_SWITCH]	traffic offered from LEC to each IEC switch including effects of damage
	ACSiec[MAX_SWITCH]	traffic offered to IEC switch for inter-switch transport
	ACStest[MAX_SWITCH]	temporary testing of ACS
	PropIntra[MAX_SWITCH]	proportion of inter-switch traffic at each IEC switch
	D3[MAX_POP]	traffic offered from LEC to each POP
	D3live[MAX_POP]	traffic offered from LEC to each POP in the case of no network damage
	D3test[MAX_POP]	temporary testing of D3
	ACPied[MAX_POP]	traffic through each POP engineered for inter-switch transport
	AC[MAX_EO]	traffic offered from each EO
	Morph[MAX_SWITCH] [MAX_SWITCH] , MorphRow[MAX_SWITCH]	holds the proportions matrix elements, and a row sum respectively, read in from the traffic distribution input file
	Lmult[MAX_LATA]	indicates regional overload multiplier for each LATA
	Rmult[MAX_REGION]	indicates regional overload multiplier assigned to each region
	ACSRegion[MAX_SWITCH] [MAX_REGION]	indicates traffic offered to each switch from each region
	AvgSwRmult[MAX_SWITCH] [MAX_REGION]	indicates the traffic-weighted average multiplier applied to each element of ACSRegion
	RmultMatrix[MAX_REGION] [MAX_REGION]	indicates the traffic multiplier applied to traffic from one region to another
double	SS[MAX_SWITCH] [MAX_SWITCH]	the main switch-to-switch proportions matrix that describes how traffic is distributed across the IEC backbone
	SSreg[MAX_SWITCH] [MAX_SWITCH]	the SS matrix after being modified to reflect regional focused overload
	SSrow[MAX_SWITCH]	sum of an SS row, used for normalizing the matrix
	F0[MAX_EO] [2]	Engineered access traffic at an EO divided by HU and final engineered proportions

	F0dmg[MAX_EO]	Engineered access traffic at an EO with damage considered
	RegF0dmg[MAX_EO]	Engineered access traffic at an EO with damage and regional overload considered
character	template[NUM_TEMP][15]	holds the labels for each section of the output file
	in_file[80]	name of network file output by sprlive
	qlink_file[80]	name of qlink file
	morph_file[80]	name of traffic distribution file
	eodmg_file[80]	name of EO damage file
	atdmg_file[80]	name of AT damage file
	popdmg_file[80]	name of POP damage file
	swdmg_file[80]	name of IEC switch damage file
	eoatdmg_file[80]	name of EO-AT span damage file
	eopopdmg_file[80]	name of EO-POP high usage span damage file
	atpopdmg_file[80]	name of AT-POP span damage file
	popswdmg_file[80]	name of POP-switch span damage file
	regovl_file[80]	name of regional overload file, if used
Local		
Variables	Variables local to main() :	
extern	integer optind, argc	command line options counters
	character *optarg, ** argv[]	reference to command line option string
character	c	general single character variable
	out_file[80]	name of output file
	keyfile[80]	name of keyfile
	line[200]	buffer for line of input from file
	temp[5]	temporary text buffer
integer	err	toggle to indicate error in command line arguments
	etog	toggle to indicate -e option
	stog	toggle to indicate -s option
	ttog	toggle to indicate -t option
	itog	toggle to indicate -i option
	otog	toggle to indicate -o option
	qtog	toggle to indicate -q option
	dtog	toggle to indicate -d option
	btog	toggle to indicate -b option
	stream	random number stream (default = 10)
	dvector	damage vector number to use (default = 1)
	early	indicates Early 1 or 2 cases (default = 0)
	done	used as a boolean in loops
	num_dead, num_tot	counts node and span damage summary statistics
	cap_live, cap_tot, cap	counts IEC TG damage summary statistics
	i,j,k,l,pm,p,m,n	general loop count variables
	test,surv,dummy	general temporary variables
float	sum_traf, sum_reg_traf	variables to count total traffic in the network
Component		
Functions	LoadKeyfile()	Loads AT&T input file list from Keyfile
	initialize()	Initializes all network and traffic variables

LoadIECData()	Loads input network file (output from sprlive)
Loadoverloads()	Loads regional overload input file
MakeRmultMatrix()	Calculates the RmultMatrix structure
MakeACSRegion()	Calculates the ACSRegion value
MakeRegionalSS()	Calculates the backbone distribution matrix for regional overload
MakeRegionalF0dmg()	Calculates the EO access traffic for regional overload
OutWrite()	Writes network and traffic variables to output file

Function Tree

Algorithmic Description

Module sprwdmg is used to apply a given damage scenario to the undamaged Sprint network description and traffic matrix. In almost every aspect, it is the same as the attwdmg module. The differences from attwdmg are described here, referencing the attwdmg module documentation where appropriate.

For attwdmg, it was assumed that backbone traffic was distributed in proportion to the trunks. In Sprint, this assumption does not hold. Therefore, sprwdmg requires an additional input file, which the sprwdmg code refers to as the morph file, to describe the undamaged traffic distribution. Refer to sprlive module documentation for more information on the calculation of this traffic distribution file.

The morph file is applied in the calculation of SS. Where attwdmg uses $IMT[i][j] / \sum IMT[i]$ to distribute switch i's traffic to all other switches j, sprwdmg replaces this term with $Morph[i][j] / MorphRow[i]$. In addition, the SS calculation for the Late case determines whether a connection exists between a pair of switches. The calculation for sprwdmg replaces the term $\sum IMT[i] == 0$ with the term $MorphRow[i] == 0$ in the "if" clauses that determines connectivity between switches.

In all other respects, sprwdmg operates identically to attwdmg.

Inputs	none
Outputs	none
returns	no formal values are returned
Purpose	To initialize all of the network and traffic variables before they are read in from the input files
Called By	main()
Calls To	none
Local Variables	
integer	i, j loop variables
Global Variables	All global network and traffic variables. See main module description.
Algorithmic Description	This function initializes all network and traffic variables. Traffic and trunk size quantities are initialized to 0. Damage vectors are initialized to 1 (survival). Popswitch[] is initialized to -1 to indicate no switch homed to each POP.

Inputs

file *inptr pointer to input IEC network file

Outputs Global network and traffic variables—described below under Algorithmic Description

returns no formal values are returned

Purpose To read in the undamaged network and traffic variables from the sprlive output file

Called By main()

Calls To none

Local Variables

integer	i, j, k, m, n, L, P, S	loop variables
	offset, count	record position and counting variables
character	line[100] , temp[15]	buffer memory

Global Variables

Global network and traffic variables—described below under Algorithmic Description.

character	template[NUM_TEMP][15]
constant	NUM_TEMP

Algorithmic Description

This function opens the undamaged network description created by sprlive. It reads in each section of the file, as indicated by the section labels in the template[] array. The following global variables are loaded from the input file:

NUMSW	AC
NUMPOP	ACSlec/ACSlec_live
NUMAT	TAP
NUMEO	SAP
ATPOPSIZE	D3/D3live
AT	ACPiec
HUPOP	popswitch
ATPOP	LATA
HAP	PhysDiv
SEP	IMT2
TEP	PropIntra
TEA	
F0	

Note that each of the 25 sections in the file may be stored in a different format and may have a different number of records depending on the variable type being read. For this reason, each section must be read in using the same formats used in sprlive when the file was written out. The dimensions, NUMSW, NUMPOP, NUMAT, NUMEO, and ATPOPSIZE, are also used to determine the sizes of the sections that follow.

Inputs

character *infile input file

Outputs

returns no formal returns

Globals:

real	Rmult	regional traffic multiplier
	Lmult	LATA traffic multiplier
integer	LReg	LATA to region mapping
	EOREg	EO to region mapping

Purpose This routine loads regional information.

Called By main()

Calls To library functions
 print_info(void)

Local Variables

double	multiplier	
character	buffer1[80] , buffer2[80]	
		working memory
integer	i, lata, region	loop variable
FILE	*inputfile	input file

Global Variables

integer	NUMREGIONS
	NUMEO
	EOLata
	EO_SIZE

Algorithmic Description

Loadoverloads() first opens the indicated file. For each region, it then retrieves the region designation and multiplier. It then reads one line for each LATA in the region. The overload and region designation for the lata is then set. Loadoverloads() then closes the file, and sets the region for each EO.

Inputs none

Outputs

returns no formal returns

Globals:

real RmultMatrix

Purpose This routine generates a matrix of region to region traffic multipliers..

Called By main()

Calls To library functions

**Local
Variables**

integer i, j loop variable

**Global
Variables**

real Rmult

**Algorithmic
Description**

This routine builds a symmetric region to region traffic multiplier matrix. The region to region traffic multiplier is taken as the max of the two regional multipliers.

Inputs	none	
Outputs		
global	float	ACSRegion[NUM_SWITCH][NUM_REGION]
returns	no formal values are returned	
Purpose	To categorize switch access traffic by region of origin for a regional focused overload run	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable
Global Variables		
integer	EOREg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	post-damage engineered access traffic at an EO
Algorithmic Description	This function sums up F0dmg for each EO to its home switch based on the region, EOREg, in which the EO is located. Its purpose is to aggregate and track, at the IEC switch level, the originating region of all access traffic. This result is important for calculating the regional SS matrix in function MakeRegionalSS().	

Inputs	none	
Outputs		
global	float	AvgSwRmult[NUM_SWITCH][NUM_REGION]
	float	SSreg[NUM_SWITCH][NUM_SWITCH]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	i, j	loop variables on dimension NUMSW
	Ri, Rj	loop variables on dimension NUMREGION
Global Variables		
integer	EOReg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	ACSlec_dam	for every switch, indicates post-damage access traffic before regional overload is assessed
	RmultMatrix	regional overload affect for every pair of originating and terminating regions
	ACSRegion	access traffic offered from each region through each switch
	SS	non-regional backbone traffic distribution
Algorithmic Description	<p>This function calculates the regional focused overload affect for each switch pair and stores the result in SSreg. For every switch pair, traffic is examined for every possible pair of regions between the switches. Each element of this traffic is subjected to overload defined by RmultMatrix. For example, from region Ri at switch i, to region Rj at switch j, traffic is overloaded by RmultMatrix[Ri][Rj]. These elements are weighted base on traffic at both ends, summed for all region combinations, and normalized to determine the average overload between the switch pair. This quantity, SStemp/ACSlec_dam, is multiplied by the original SS value to yield a regional overloaded SSreg value.</p> <p>Note that an important intermediate result, AvgSwRmult, is calculated along the way. This value is the average focused-overload-induced multiplier applied to traffic leaving region Ri through switch i. It is computed from the overload experienced from region Ri at switch i to every other region/switch combination, Rj and j. This result has intentionally not been weighted by access traffic. This allows it to be used on a case-by-case basis for various access traffic values, as seen in function MakeRegionalF0dmg().</p>	

Inputs	none	
Outputs		
global	float	RegF0dmg[NUM_EO]
returns	no formal values are returned	
Purpose	To compute the affect of regional focused overload on the backbone traffic distribution, and to measure the traffic-weighted overload created by regional affects for each originating switch/region combination.	
Called By	main()	
Calls To	none	
Local Variables		
integer	k	loop variable on dimension NUMEO
Global Variables		
integer	E0Reg	for every EO, indicates the region it is in
	SW	for every EO, indicates its unique homed IEC switch
float	F0dmg	for every EO, indicates the engineered access traffic prior to regional focused overload affects
	AvgSwRmult	indicates the traffic-weighted average regional focused overload experienced by access traffic from each region through each switch
Algorithmic Description	This function calculates RegF0dmg for every EO. This quantity is a function of the post-damage engineered access traffic at the EO, F0dmg, and the average overload caused by regional overload effects, AvgSwRmult. AvgSwRmult, in turn, is a function of what region the EO resides in, and what switch it is homed to. For a regional focused overload, RegF0dmg represents the load offered at the EOs to the IEC.	

Inputs

file *outptr pointer to output damaged IEC network file

Outputs Global network and traffic variables are written to file—described below under Algorithmic Description

returns no formal values are returned

Purpose To write out all the damaged network and traffic variables to the output file

Called By main()

Calls To none

Local Variables

integer k, l, m, n loop variables

Global Variables

Global network and traffic variables—described below under Algorithmic Description.

Algorithmic Description

This function writes a carrier-specific header to the output file, followed by the global damaged network and traffic variables. Each variable is written to a labeled section, with the following description:

IECid	identifies the carrier (att, mci, or spr)
SWITCH_SIZE	number of IEC switches in the network
POP_SIZE	number of POPs in the network
AT_SIZE	number of ATs in the network
EO_SIZE	number of EOs in the network
ATPOPSIZE	maximum number of POPs an AT homes to for this network
EOAT	for every EO, identifies the homed AT (-1 if N/A)
HUPOP	for every EO, identifies the homed HU POP
ATPOP	for every EO, identifies the homed POP through the AT
HAP	for every AT, identifies all homed POPs
SD	for every EO, identifies the size of the EO-POP TG
TEA	for every EO, identifies the total (both ways) traffic engineered for the EO-AT TG
F0	for every EO, identifies the components of access traffic offered to the HU and final homings respectively
F0dmg	for every EO, identifies the amount of engineered access traffic offered by the EO after damage affects are considered
ELAP	for every AT, identifies the total AT-POP traffic for each AT-POP homing defined in HAP
SAP	for every AT, identifies the size of each AT-POP TG
ACS	for every IEC switch, identifies the total access traffic offered for inter-switch transport
POPSWITCH	for every POP, identifies the homed IEC switch
AC1	for every EO, identifies the actual traffic offered, including regional focused overload, if applicable

EOalive	for every EO, indicates 0/1 for failure/survival
ATalive	for every AT, indicates 0/1 for failure/survival
POPalive	for every POP, indicates 0/1 for failure/survival
SWalive	for every switch, indicates 0/1 for failure/survival
EOLata	for every EO, identifies its LATA
PhysDiv	for every EO, identifies if the HU homing (if any) is physically diverse from the final homing (if any)
SS	for the matrix of IEC switch pairs, identifies traffic distribution from one switch to the other
SSreg	same as SS, but for regional focused overload
PropIntra	for every switch, indicates the proportion of access traffic that is intra-switch traffic

Note that each of the sections in the file may be stored in a different format and may have a different number of records depending on the variable type being written.

3.10 merge: Merge of IEC Files

Purpose	This is the main module for merging the iec2lecam.step2 files		
Call Syntax	mkrout -k <key file> [options] <i>mandatory:</i> <i>special syntax:</i> <i>function</i> none <i>options:</i> <i>special syntax:</i> <i>function:</i> -k <input key file> reads in input file -? user help—prints call syntax and exits without running		
example	merge -k	keyfile	
Input Files	The files listed below are input through a command line option.		
	IEC_SIZE	IEC data file	
Output Files	outfile	This file contains the results of the combined .step2 files	
Includes	"fileio.c"	User-defined I/O functions; see Appendix A	
	"lecam.h"	User-defined I/O functions	
Constants	A005	211.10	traffic reqd for P.005 on 250 trunks
	A01	214.60	traffic reqd for P.01 on 250 trunks
Global Variables			
integer	KEYTOG=0	keyfile toggle	
	IEC_SIZE	size of the IEC	
	SWITCH_SIZE[MAX_IEC]	size of the IEC switch	
	POP_SIZE[MAX_IEC]	size of the POP	
	AT_SIZE	size of the AT	
	EO_SIZE	size of the EO	
	ATPOPSIZE[MAX_IEC]	size of the AT to POP connection	
	EOAT[MAX_EO]	size of the EO to AT connection	
	HUPOP[MAX_EO][MAX_IEC]	amount of traffic on the HU to POP connection	
	ATPOP[MAX_EO][MAX_IEC]	amount of traffic on the AT to POP connection	
	HAP[MAX_IEC][MAX_AT][ATPOPMAX]	amount of traffic on the HU-AT to POP connection	
	SD[MAX_EO][MAX_IEC]	number of trunks EO to AT	
	SAP[MAX_IEC][MAX_AT][ATPOPMAX]	number of trunks AT to POP	
	POPSWITCH[MAX_IEC][MAX_POP]	location of the POP switch	
	EOalive[MAX_EO]	surviving EO	
	ATalive[MAX_AT]	surviving AT	
	POPalive[MAX_IEC][MAX_POP]	surviving POP	

	SWalive[MAX_IEC][MAX_SWITCH]	surviving Switch
	Eolata[MAX_EO]	LATA associated with each EO
	PhysDiv[MAX_EO][MAX_IEC]	co-location indicator
real	SS	the engineered prop of traffic from SW S1 to each SW S2 norm by row
	Ssreg	the proportion of traffic from SW S1 to each SW S2 normalized by row
kc2type	F0	total access traffic from EO k to IEC c ([0]HU [1]FINAL)
kctype	F0dmg	access traffic with damage from EO k to IEC
	AC1	access traffic at EO k destined for IEC c
cLptype	ELAP	engineered load on AT-POP TG for AT L and POP P in IEC c
cStype	ACS	engineered level of access traffic at SWITCH S
character	template[27][15] =	{"IECid","SWITCH_SIZE","POP_SIZE","AT_SIZE","EO_SIZE","ATPOPSIZE","EOAT","HUPOP","ATPOP","HAP","SD","TEA","F0","F0dmg","ELAP","SAP","ACS","POPSWITCH","AC1","EOalive","ATalive","POPalive","SWalive","Eolata","PhysDiv","SS","SSreg"};
	inputfile[MAX_IEC][80]	name of the input file
	outputfile[MAX_IEC][80]	name of the output file
	qfile[MAX_IEC][80]	name of the QTCM file
	IECid[MAX_IEC][5]	IEC inidicator (att/mci/spr)
Local		
Variables	Variables local to main()	
extern	character	*optarg
	integer	optind
	a string containing a single command line argument.	
	the number of single command line arguments to be processed, supplied externally by the operating system	
character	c	a command line option character
	filelist[80]	holds the name of the input key file
	**argv[]	an array containing all of the command line arguments
integer	tog=0	error flag indicating a problem with the command line arguments
	argc	the number of command line arguments
Component		
Functions	LoadKeyFiles()	loads input key files
	LoadIECData()	loads IEC data
	MakeMainFile()	formats and writes output file

Function Tree

Algorithmic Description

This module is used to merge the three iec .step2 files:

- att2lecam.step2
- mci2lecam.step2
- spr2lecam.step2

Inputs

character *keyfile pointer to an input file

Outputs

returns no formal returns

FILE *inputfile points to the input file containing the
TAMI.iec2lecam.step2 data
*qfile points to the TAMI.qtcn.iec qtcn data file
*outputfile points to the TAMI.dp.iec output file

Purpose This routine loads

Called By main()

Calls To none

Local Variables

character line[80] used for parsing the input file

integer i loop count variable
count=0 loop count variable
att=0 iec toggle
mci=0 iec toggle
spr=0 iec toggle

FILE *fptr pointer to an input file

Global Variables

none

Algorithmic Description

For each iec, this routine loads the names of the input files into the appropriate input, output and qtcn files.

Inputs		
integer	c	loop count variables
FILE	*fptr	points to an output file
Outputs		
integer	KEYTOG=0	keyfile toggle
	IEC_SIZE	size of the IEC
	SWITCH_SIZE[MAX_IEC]	size of the IEC switch
	POP_SIZE[MAX_IEC]	size of the POP
	AT_SIZE	size of the AT
	EO_SIZE	size of the EO
	ATPOPSIZE[MAX_IEC]	size of the AT to POP connection
	EOAT[MAX_EO]	size of the EO to AT connection
	HUPOP[MAX_EO][MAX_IEC]	amount of traffic on the HU to POP connection
	ATPOP[MAX_EO][MAX_IEC]	amount of traffic on the AT to POP connection
	HAP[MAX_IEC][MAX_AT][ATPOPMAX]	amount of traffic on the HU-AT to POP connection
	SD[MAX_EO][MAX_IEC]	
	SEA[MAX_EO]	number of trunks EO to AT
	SAP[MAX_IEC][MAX_AT][ATPOPMAX]	number of trunks AT to POP
	POPSWITCH[MAX_IEC][MAX_POP]	location of the POP switch
	EOalive[MAX_EO]	surviving EO
	ATalive[MAX_AT]	surviving AT
	POPalive[MAX_IEC][MAX_POP]	surviving POP
	SWalive[MAX_IEC][MAX_SWITCH]	surviving Switch
	EOLata[MAX_EO]	LATA associated with each EO
	PhysDiv[MAX_EO][MAX_IEC]	co-location indicator
real	SS	the engineered prop of traffic from SW S1 to each SW S2 norm by row
	Ssreg	the proportion of traffic from SW S1 to each SW S2 normalized by row
kc2type	F0	total access traffic from EO k to IEC c ([0]HU [1]FINAL)
kctype	F0dmg	access traffic with damage from EO k to IEC
	AC1	access traffic at EO k destined for IEC c
cLType	ELAP	engineered load on AT-POP TG for AT L and POP P in IEC c
cStype	ACS	engineered level of access traffic at SWITCH S
character	template	IEC data template

	inputfile	holds the name of the input file
	outputfile	holds the name of the output file
	qfile	holds the name of the QTCM file
	IECid	identified the IEC
returns	no formal returns	
Purpose	This routine loads the IEC data for each IEC	
Called By	main()	
Calls To	none	
Local Variables		
integer	i, j, k, L, P, S offset count	loop count variables used to parse a line of the input file loop count variable
FILE	*outptr	points to an output file
character	line[100] temp[10]	used to hold a line of input from the input file used to hold a line of input from the input file
Global Variables		
character	line[LINE_LENGTH]	length of input line
Global Constants		
	none	
Algorithmic Description	Reads the IEC data fields listed as outputs and loads them into the output file.	

Inputs

FILE	*fptr	pointer to the output file
------	-------	----------------------------

Outputs

returns	no formal returns
---------	-------------------

Purpose	To produce the output file.
----------------	-----------------------------

Called By	main()
------------------	--------

Calls To	none
-----------------	------

Local Variables

integer	k, c, L, P, S count	loop count variables loop count variable
real	x	used to track traffic EO to AT

Global Variables

integer	num_11=0 num_13=0 num_33=0	number of class1 to class1 switch pairs number of class1 to class3 switch pairs number of class3 to class3 switch pairs
character	line[LINE_LENGTH]	length of input line

Algorithmic Description

This routine prints out the output data file for the datafields listed as Global Variables for this module.

3.11 LECAM: Determines Overall PSN Blockage

Purpose LECAM is the module of TAMI which offers traffic at the EO level and calculates subsequent blockages in every TG in the PSN. This module contains the code which loads the IEC and LEC datafiles (including network topology, physical damage, and offered traffic) and performs LEC blockage calculations. For IEC blockages, LECAM calls QTCM for each IEC. The code which performs the summary calculations for overall PSN blockage is contained in calcbigh.c.

Call Syntax `lecam -i <input file> [options]`

<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
-i	<input file>	reads in input file
 <i>options:</i>	 <i>special syntax:</i>	 <i>function:</i>
-d		DOC ON/OFF
-p		use Poisson blockage ON/OFF
-f		flush screen buffer (for debug)
-o	<outfile>	output logfile
-c	<filename>	CSI link file
-m	<float>	access traffic multiplier
-b	<integer>	initial number of pairs sampled
-s	<integer>	random number stream (1-15)
-e	<1 2>	turn on early-post-disaster rules
-C		enable count of ALL connected pairs through all IECs
-v		init assumed variables with final values from prev run
-n	<filename>	Use NS/EP traffic matrix nij_file
-r	<filename>	Use Regional
-A		Turn Glare Off
-B	<float>	Set DOC Level
-D		Turn Matching Loss Off
-E		Use High Matching Loss Levels
-F	<float>	Set Matching Loss Level
-x		cancel PrintResults
-l		use LEC TCR in select LATAs
-?		help

example `lecam -i TAMI.dp.main -l -m 1.25 -d -e1 -n traffic_mat`

Input Files

**regional
overloads** This file contains region definitions and traffic overloads

format R<#> <overload value>
The region number, and traffic overload value
<LATA #>
[<LATA #>
...]
A list of LATAs in the region

```
[ R<#> <overload value>
<LATA #>
[ <LATA #>
... ]
... ]
```

A list of region definitions, as above.

main datafile Contains LEC assets and sizings, damage vectors, and LATA definitions. It also contains the names of the IEC input data files, and the total number of IECs under consideration.

format IEC_SIZE <#>
Beginning in column 13, the number of IECs under consideration.

IECfiles
<3-character IEC id> <IEC data file>
Beginning in column two, the three character IEC identifier. Then at column five, the filename (pathname) of the datafile for the referenced IEC.

AT_SIZE <#>
Beginning in column 13, the number of ATs in the model.

EO_SIZE <#>
Beginning in column 13, the number of EOs in the model.

EOAT
<4-character AT index><4-character AT index>...
For each EO, a four column identifier for its homed AT. These four character indexes are arranged twenty to a line.

SEA
<5-character size><5-character size>...
For each EO, a five character size of the EO-AT trunk. These blocks are arranged 15 to a line.

EOalive
<1|0><1|0><1|0><1|0>...
For each EO, a single character (1 or 0) indicating whether that EO is to be considered alive in this run. Arranged 80 to a line.

ATalive
<1|0><1|0><1|0><1|0>...
For each AT, a single character (1 or 0) indicating whether that AT is to be considered alive in this run. Arranged 80 to a line.

EOLata
<4-character LATA #><4-character LATA #>...
For each EO, a four column identifier for its LATA. These four character identifiers are arranged twenty to a line.

IEC datafiles Contains IEC assets and sizings, damage vectors, and default traffic distributions.

format SWITCH_SIZE <#>
Beginning in column 13, the number of switches belonging to this IEC which are in the model.

POP_SIZE <#>

Beginning in column 13, the number of POPs in the model.

AT_SIZE <#>

Beginning in column 13, the number of ATs in the model.

EO_SIZE <#>

Beginning in column 13, the number of EOs in the model.

ATPOPSIZE <#>

Beginning in column 13, the number of AT-POP trunks belonging to this IEC which are in the model.

QTCMfile <filename>

Beginning in column nine, the filename (pathname) of the QTCM datafile for the referenced IEC.

HUPOP

<4-character POP index><4-character POP index>...

For each EO, a four column identifier for any direct POP HU trunk.

These four character indexes are arranged twenty to a line.

ATPOP

<4-character POP index><4-character POP index>...

For each EO, a four column identifier for any AT-POP trunk. These four character indexes are arranged twenty to a line.

HAP

<4-character POP code><4-character POP code>...

<4-character POP code><4-character POP code>...

<4-character POP code><4-character POP code>...

...

For each AT, and each POP for the current IEC, a four character code indicating whether the AT is homed to that POP.

SD

<5-character size><5-character size>...

For each EO, a five character size of the EO-POP HU trunk. These blocks are arranged 15 to a line.

F0

<8-character traffic value 0><8-character traffic value 1>

<8-character traffic value 0><8-character traffic value 1>

...

For each EO, a line with two eight character traffic values.

F0dmg

<8-character traffic value>

<8-character traffic value>

...

For each EO, a line with an eight character traffic values.

ELAP

<8-character traffic value><8-character traffic value >...

<8-character traffic value><8-character traffic value >...

<8-character traffic value><8-character traffic value >...

...

For each AT, and each POP for the current IEC, an eight character engineered access traffic load value.

SAP

<4-character trunk size><4-character trunk size >...

<4-character trunk size ><4-character trunk size >...

<4-character trunk size ><4-character trunk size >...

...

For each AT, and each POP for the current IEC, an eight character trunk size.

ACS

<8-character traffic value><8-character traffic value >...

For each switch an eight character engineered access traffic load value. These are arranged ten to a line.

POPSWITCH

<4-character switch code><4-character switch code>...

<4-character switch code><4-character switch code>...

<4-character switch code><4-character switch code>...

...

For each POP, and each switch for the current IEC, a four character code indicating whether the POP is homed to that switch.

AC1

<8-character traffic value><8-character traffic value >...

For each EO an eight character engineered access traffic load value. These are arranged ten to a line.

POPalive

<1|0><1|0><1|0><1|0>...

For each POP in the current IEC, a single character (1 or 0) indicating whether that POP is to be considered alive in this run. Arranged 80 to a line.

SWalive

<1|0><1|0><1|0><1|0>...

For each switch in the current IEC, a single character (1 or 0) indicating whether that switch is to be considered alive in this run. Arranged 80 to a line.

PhysDiv

<1|0><1|0><1|0><1|0>...

For each EO, a single character (1 or 0) indicating whether that EO's HU is physically diverse from its AT-POP final. Arranged 80 to a line.

SS
 <8-character traffic value><8-character traffic value >...
 <8-character traffic value><8-character traffic value >...
 <8-character traffic value><8-character traffic value >...

A square switch-switch matrix of eight character values indicating the proportion of traffic destined from one switch to the other.

SSregress
 <8-character traffic value><8-character traffic value >...
 <8-character traffic value><8-character traffic value >...
 <8-character traffic value><8-character traffic value >...
 ...

A square switch-switch matrix of eight character values indicating the proportion of traffic destined from one switch to the other. This is normalized by column.

TAMI.finalvalues

Carryover results from the previous iteration.

format OLAT
 <OLAT value> <OLAT value> <OLAT value>...
 A value for each AT traffic overload.

OLEO
 <OLEO value> <OLEO value> <OLEO value>...
 A value for each EO traffic overload.

For each IEC:
 e2 and SWBlock
 <e2 value> <e2 value> <e2 value>...
 An egress blockage value for each AT-POP trunk.

<SWBlock value><SWBlock value>...
 Switch to switch blocking values.

traffic sample file
 EO-EO traffic values for randomly selected EO pairs.

format <EO index #> <EO index #> <traffic value>
 The first two integers index EOs. Beginning at column 12, a floating point number representing the offered traffic between that pair.

ppmeanfile.<att|mci|spr>
 Average IEC blockage, and switch to switch IEC blockage.

format <average blockage value>
 <7-character traffic value><7-character traffic value>...
 <7-character traffic value><7-character traffic value>...

<7-character traffic value><7-character traffic value>...

A square switch-switch matrix of seven character values indicating the blockage from one switch to the other.

Traffic Matrix

EO-EO pair traffic values

format <EO 1> <EO 2> <traffic value>
...

A listing of EO pairs, followed by the traffic between them.

Output Files

TAMI.finalvalues

As documented above.

TAMI.lecam.qtcn.temp

Documented as a QTCM input file.

screen output(captured to TAMI.latest_lecam_outfile when invoked from tami.c)

This basic file structure may be interspersed with warning messages printed by LECAM.

format

DOC = <#>
[DOC invoked at = <#>]
<EARLY|LATE> POST-DISASTER MODE
Traffic Multiplier: <#> times.
<#> outer loops on SWBlock (QTCM).
<#> inner loops on e2 (on average).
<#> innermost loops on EO and AT overload (on average).
Fairly self-explanatory settings and convergence reporting.

OLEO and Blockage on EO TGs:
EO <EO index> (<0=dead|1=alive>): OL=<#> (a1=<#>, e1=<#>)
...

For each EO, its index, alive state, overload and blockages.

EO <EO index> (<0=dead|1=alive>): OL=<#> (a1=<#>, e1=<#>)
(a3=<#>).(a0=<#>, e0=<#>)...

For each EO, its index, alive state, overload and blockages.

OLAT and Blockage on AT-IEC TGs (a2,e2)
AT <AT index> (<0=dead|1=alive>) OL=<#>
IEC<IEC id #>: a2=<#> e2=<#>
...

For each AT, its index, alive state, overload and blockages broken out by carrier.

TAMI.lecamlog

Keeps a running log of LECAM results.

format <EARLY|LATE> POST-DISASTER MODE
Traffic Multiplier[s] : <<#> times | [R<#>=<#>]
[R<#>=<#>]
...>
Traffic overloading. If a regional analysis, several lines of region/overload pairs.

[DOCLEVEL: #]
If DOC has been invoked, the traffic level (multiple of engineered load) at which it becomes active.

[*** OSCILLATION DETECTED: <#> <OL|e2|SWBlock> variables] ...
Warns of oscillations in the three variable classes for which this is tested, and gives the number of variables oscillating.

Survival data:
EOs..... <%>
ATs..... <%>
POPs..... [<%> (IEC <IEC id #>)]
[<%> (<IEC id #>)]
...
Switches.... [<%> (IEC <IEC id #>)]
[<%> (<IEC id #>)]
...
EO-POP TGs.... [<%> (IEC <IEC id #>)]
[<%> (<IEC id #>)]
...
AT-POP TGs.... [<%> (IEC <IEC id #>)]
[<%> (<IEC id #>)]
...
EO-AT TGs..... <%>

The percentage of surviving assets of the indicated type.

POTS Traffic Totals for IEC <IEC id #> (<IEC id>):
DOC engineered= <#>
NO DOC engineered= <#>
offered to EO= <#>
offered after DOC= <#> (<%>) (<%>)
offered to IEC= <#> (<%>) (<%>)
completed thru IEC= <#> (<%>) (<%>)
completed to EO= <#> (<%>) (<%>)
percent blocked= <#> (<%>) (<%>)

For each IEC, cumulative statistics on traffic blockage across each major PSN component.

TOTAL ENGINEERED TRAFFIC: <#> erlangs (<%>%,
[<%>%,] ...)
TOTAL OFFERED TRAFFIC: <#> erlangs (<%>%,
[<%>%,])
TOTAL COMPLETED TRAFFIC: <#> erlangs (<%>%,
[<%>%,] ...)

Traffic totals for each IEC.

Connectivity Analysis:
PSN : POTS=<#>
NSEP/RTNR=<#>

```

[ NSEP/CSI=<#>]
IEC <#> (<IEC id>): POTS=<#>
  NSEP/RTNR=<#>
  [ NSEP/CSI=<#>]

```

...

The percentage connectivity for the PSN and each IEC.

```

BIGBPOTS=<#>
>BIGBPOTS<IEC id>=<#>
BIGBSAMPr<region1>r<region2>=<#>
>BIGBSAMPr<region1>r<region2><IECid>=<#>

```

...

Traffic-weighted blockage values for the PSN based on POTS traffic, and the provided traffic sample, respectively.

```

BIGBRTNR<0|1>Or<region1>r<region2>=<#>
>BIGBRTNR0r<region1>r<region2><IECid>=<#>

```

...

```

BIGBCSI<0|1>r<region1>r<region2>=<#>
>BIGBCSIr<region1>r<region2><IECid>=<#>

```

...

```

BIGBTCR<0|1>r<region1>r<region2>=<#>
>BIGBTCR0r<region1>r<region2><IECid>=<#>

```

...

```

BIGBLEC<0|1>r<region1>r<region2>=<#>
>BIGBLEC0r<region1>r<region2><IECid>=<#>

```

...

The blockages associated with the addition of each indicated program (RTNR, CSI, IEC TCR, LEC TCR). The <0|1> indicates whether the traffic weighting used supplied sample traffic. One block is printed for each region-region pair.

```

BIGBCONNpsn=<#>
BIGBCONNpsnr=<#>
[ BIGBCONNpsn_csi=<#>]

```

The connectivity associated with the addition of each indicated program (RTNR, CSI).

```

BIGBCONN<IEC id>=<#>
[ BIGBCONNrtnr=<#>]
[ BIGBCONNcsi=<#>]

```

The connectivity associated with the addition of each indicated program (RTNR, CSI).

Includes	<stdio.h>	Standard 'c' defined I/O functions.
	<math.h>	Standard 'c' defined math functions.
	"fileio.c"	User-defined I/O functions; see Appendix A.
	"lecam.h"	User-defined typedefs and defines.

Constants	TEST_SW_R1	debugging switch
	TEST_EO_R1	debugging switch
	TEST_SW_R0	debugging switch
	TEST_EO_R0	debugging switch

from lecam.h

TRUE	1	true
FALSE	0	false

MAX_IEC	3	max number of IECs in model
MAX_AT	1000	max number of ATs in model
MAX_EO	19250	max number of EOs in model
ATPOPMAX	9	max number of POPs a single AT may home to
MAX_POP	575	max number of POPs in an IEC
MAX_SWITCH	130	max number of switches in an IEC
MAX_LATA	1000	max number of LATAs in model

	bcount	loop counters
	Olcount	
	e2count	
	totalOlcount	loop counters
	totale2count	
	b_not_converge[2]	number of variables not converged from prev two iterations
	e2_not_converge[2]	
	ol_not_converge[4]	number of variables not converged from prev four iterations
	b_oscillation	zero if no oscillation detected, otherwise holds number of oscillation variables
	e2_oscillation	
	ol_oscillation	zero if no oscillation detected, otherwise holds number of oscillation variables
	FirstLoop	toggle to indicate the first iteration
	EOAT[MAX_EO]	the AT to which EO k is homed (-1 if none)
	HUPOP[MAX_EO][MAX_IEC]	the POP in IEC c to which EO k is homed for HU
	ATPOP[MAX_EO][MAX_IEC]	the POP in IEC c to which EO k is homed for final traffic (-1 if none)
	HAP[MAX_IEC][MAX_AT][ATPOPMAX]	the POP(s) in IEC c to which an AT L is homed (-1 if none)
	SD[MAX_EO][MAX_IEC]	the size of the HU TG from EO k to IEC c (0 if none)
	POPSWITCH[MAX_IEC][MAX_POP]	the switch to which POP P is homed for IEC c (-1 if none)
	EOSW[MAX_EO][MAX_IEC]	returns the homed IEC c switch given EO k
	attnum	
	mcinum	
	sprnum	
long integer	long_count	long integer counter for big loops
	long_count2	long integer counter for big loops
char	input_file[80]	main input data file
	nij_file[80]	Nij filename (NS/EP)
	IECfiles[MAX_IEC][80]	names of each IECs data files
	QTCMfile[MAX_IEC][80]	names of each IECs QTCM data file
	CSIfile[80]	names of CSI link file (optional)
	IECid[MAX_IEC][5]	three-character IEC identifier: att, mci, spr
	regressovl_file[80]	name of regional overload file (optional)
	MainTemplate[9][15]	{"IEC_SIZE", "IECfiles", "AT_SIZE", "EO_SIZE", "EOAT", "SEA", "EOalive", "ATalive", "EOlata"}
		order of variables in main data file
	SubTemplate[22][15]	{"SWITCH_SIZE", "POP_SIZE", "AT_SIZE", "EO_SIZE", "ATPOPSIZE", "QTCMfile", "HUPOP", "ATPOP", "HAP", "SD", "F0", "F0dmg", "ELAP", "SAP", "ACS", "POPSWITCH", "AC1", "POPalive", "SWalive", "PhysDiv", "SS", "SSreg"}
		order of var in IEC data files

Local Variables		Variables local to main()
integer	err=0	error flag indicating a problem with the command line arguments
	argc	the number of command line arguments
	i, j	loop counter variables
	current_bin	
	vector_offset	
	OPTOG	indicates command line options

Algorithmic Description

This is the functional heart of TAMI. LECAM calculates and messages traffic based on requested parameters. It invokes QTCM to calculate IEC and LEC trunk blockages. It iterates on traffic and blockage levels until it reaches steady state. It gathers and processes statistics on traffic and blockages.

LECAM first processes command line arguments. It then loads data from IEC and LEC networks, passing the name of the `input_file` to `LoadData()`. If a regional analysis is being performed, overloads are then loaded and the multiplier matrix calculated using `Loadoverloads()` and `MakeRmultMatrix()`.

The next section of LECAM performs a number of calculations to initialize traffic and blockage values. If `InitPrev` is set, LECAM seeks previous final values, and uses those as an initialization set. These values are retrieved in `LoadPrevValues()`. The variable `fptr`, which is passed into `LoadPrevValues()`, is a FILE pointer, initialized to the hardcoded "TAMI.finalvalues". The code sections until the label `AA`: specify adjustments to base traffic levels based on global overloads, damaged locations, regional overloads and high usage bypasses.

The code segments which follow, up to the comment stating "Calculate sum of AC1 and F0dmg by region," comprise the central iterations of TAMI. These code pieces are organized in an inner and outer loop. The inner loop begins at the label `AA1`: and ends at the statement `fprintf(stderr, "> Running QTCM for each IEC."` This loop tests the LEC-IEC interface, attempting to converge on egress traffic. This is logically equivalent to convergence on blockages. At each iteration the inner loop adjusts traffic based on DOC and regional factors. It also uses `CalcAE()`,

a local routine, to determine LEC-IEC trunk traffic flows where trunk glare is a factor. In calculating blockages, this inner loop makes great use of the routines `PoissonB()` and `ErlangB()` from `traffic.c`. The inner loop also has several startup facilities controlled by the `Firstloop` variable. At each iteration, the inner loop seeks convergence on `e2` and `e2new` - the previous and current egress traffic measures. It also seeks to determine if the egress traffic variables are oscillating. It abandons the loop and prints a warning message if it detects such oscillations. In the event that neither oscillation nor convergence are detected, the program branches (using `goto` statements) back to `AA1` :

The outer loop is structured much like the inner loop. It tests for convergence or oscillation on `SWBlock` - the blockage at switches. In each iteration it initializes variables, executes the inner loop, invokes QTCM to determine IEC switch blockages, tests for convergence or oscillation, and branches to the label `AA` : (using `goto` statements) if further iterations are necessary. QTCM is invoked through several steps: creating a `TAMI.qtc_inp` from hardcoded data; creating a carrier-specific qtc file using `MakeQFile()`; invoking a carrier-specific version of QTCM (`qmod_att`, `qmod_mci`, `qmod_spr`); and finally retrieving the results generated by QTCM in the routines `QResult()` and `ReadQMatrix()`.

Following the outer loop, `lecam` produces a number of reports and data files based on the calculated traffic and blockage levels. A seed for the next iteration is generated in the routine `DumpFinalValues()`, which directs this information to a file. The routine `PrintResults()` generates screen output. The next section of code calculates connectivity statistics, calling the routine `connect()`. The final code segment samples EO pairs to determine end-to-end blockages. The sampling and calculations are performed in `CalcBigB()`. `AddPriority` calculates the same blockage numbers including priority routing mechanisms, as determined by switches set by the command line arguments. `LogResults()` prints these end-to-end and connectivity statistics to a running log file. `LECAM` then exits gracefully.

Inputs

FILE *fptr input file

Outputs

returns no formal returns

Globals:

ctype offdtraffic

Purpose

This routine writes selected results to the indicated file.

Algorithmic

Description

LogResults() prints the final results of the congestion analyses to the file indicated by fptr. It also calculates summary statistics in place.

Inputs

character infile

Outputs

returns no formal returns

Purpose This routine loads file names from the keyfile specified in the command line of
tami.c.

Called By main()

Calls To LoadMainFile(), LoadSubFile()

**Local
Variables**

integer	c	IEC index counter
FILE	*fptr	points to the primary input file

**Global
Variables**

char	IECfiles	names of IEC inputfiles
------	----------	-------------------------

**Algorithmic
Description**

This routine is a programming interface piece that points to the two routines that load all the basic data for LECAM; LoadMainFile() and LoadSubFile().

Inputs

FILE * fptr

Outputs

returns no formal returns

Globals:

```

int    IEC_SIZE
       AT_SIZE
       EO_SIZE
       EOAT
       SEA
       EOalive
       ATalive
       EOlata
char    IECid
       IECfiles

```

Purpose This routine loads global definition data. It also provides LoadData () with the names of the IEC specific data files.

Called By LoadData ()

Calls To library functions

Local Variables

```

character  line[ 100]      used to parse a line of input
           temp[ 10]      used to parse a line of input

integer    i, j, k, c, L, count, n
           a variety of counters

double     x               place holder for average taking

```

Global Variables

```

char    MainTemplate

```

Algorithmic Description

LoadMainFile () reads data in the file indicated by fptr. The data is partitioned into nine sections, each labeled. The global MainTemplate is an array of strings, initialized with the section headings for the main data file, in the proper order. The primary loop in this section is over the sections. The switch statement is used as a jump table, with specific code for each section, and the index dictated by the MainTemplate entry corresponding to the current section header. The parsing of individual sections is straightforward, and well commented in the code.

Inputs

integer	c	carrier index
character	filename[]	name of the data file

Outputs

returns	no formal returns
---------	-------------------

Globals:

kctype	AC1
	AC1Prime
int	POPSwitch
cStype	ACS
int	SAP
cLPtype	ELAP
kctype	FODmg

cSStype	SS
	SSTNG
char	QTCMfile

Purpose	This routine loads carrier-specific information from the named file.
----------------	--

Called By	LoadData()
------------------	------------

Calls To	library functions
-----------------	-------------------

Local Variables

FILE	*fptr	
character	line[100]	
	temp[10]	
integer	i, j, k, c, L, count, n	a variety of counters
double	x, y	helpers for averaging

**Global
Variables**

int AT_SIZE
 EO_SIZE

**Algorithmic
Description**

LoadSubFile() reads data in the file indicated by filename for the carrier indicated by c. The data is partitioned into 22 sections, each labeled. The global SubTemplate is an array of strings, initialized with the section headings for the carrier data file, in the proper order. The primary loop in this section is over the sections. The switch statement is used as a jump table, with specific code for each section, and the index dictated by the SubTemplate entry corresponding to the current section header. The parsing of individual sections is straightforward, and well commented in the code.

Inputs

FILE * fptr

Outputs

returns no formal returns

Globals:

Ltype OLAT
 ktype OLEO
 cLPtype e2
 cSStype SWBlock

Purpose This routine loads ending values from a previous iteration as starting values for the current iteration.

Called By main()

Calls To library functions

Local Variables

FILE * fptr
 character line[50]
 integer c, L, P, k, i, PM, S a variety of counters
 double x, y helpers for averaging

Global Variables

int EO_SIZE
 AT_SIZE
 IECSIZE
 ATPOPSIZE

Algorithmic Description

LoadPrevValues() loads data from the file pointed to by fptr for the LECs and IECs. This file is formatted in three major sections, relating to LEC ATs, LEC EOs and IEC data. Within the IEC data section there are subsections for each IEC, containing data on AT-POP trunk blockages, and switch blockages.

Inputs

float	b	trunk blockage
	AC	access traffic
	EG	egress traffic

Outputs

returns	no formal returns
---------	-------------------

float	* a	final access blockage
	* e	final egress blockage

Purpose This routine calculates the proportion of access and egress traffic blocked, as determined by glare resolution

Called By main()

Calls To none

Local Variables

float	x	placeholder
-------	---	-------------

Global Variables none

Algorithmic Description

The NCS Traffic Congestion Analysis Report (Nov. 92) contains detailed derivations of the glare equations.

Inputs

int	c	carrier index
char	qtcn_file	template file name

Outputs

returns	no formal returns
---------	-------------------

Purpose This routine creates a QTCM input file based on the template file qtcn_file and the switch-to-switch traffic matrix AC14.

Called By main()

Calls To library functions

Local Variables

int	i, j, count	loop variables
char	line[100]	working storage
FILE	*inptr, *outptr	input and output files

Global Variables

cSStype	AC14	switch-to-switch traffic
---------	------	--------------------------

Algorithmic Description

MakeQFile() generates a QTCM input file, title TAMI.lecam.qtcn.tmpfile. This file is created based on template file, referenced by qtcn_file. The qtcn_file template's sections 7 is replaced by data from the current iteration, for the carrier indicated by the parameter c. This data is taken from the global variable AC14. The data is output in a transposed matrix to match QTCM's input format.

Inputs

char fname name of the ppmeanfile to be read.

Outputs

returns float aggregate blockage from fname

Purpose This routine reads the QTCM ppmeanfile for the results of the final QTCM run.

Called By main()

Calls To library files

**Local
Variables**

FILE	* fptr	input file
char	temp[8] , line[80]	working storage
float	b	result from the file

**Global
Variables** none

**Algorithmic
Description** Opens and closes the indicated ppmeanfile. This routine reads the QTCM final result from the first line.

Inputs

csstype	SWBlock	switch-to-switch blockages
int	IEC	IEC index
char	fname	name of the desired ppmeanfile

Outputs

returns	no formal returns
---------	-------------------

Globals:

cSStype	SWBlock
---------	---------

Purpose

ReadQMatrix() reads the switch-to-switch blockages produced by QTCM from the indicated ppmeanfile.

Called By

main()

Calls To

library functions

Local Variables

FILE	*fptr	input file
char	temp[8], line[100]	working storage
int	i, j, count	loop variables

Global Variables

int	SWITCH_SIZE	the number of switches in any give IEC
-----	-------------	--

Algorithmic Description

Opens and closes the indicated ppmeanfile. The first line is skipped, then this routine reads the QTCM result from the remaining lines.

Inputs none

FILE *fptr output file

Outputs

returns no formal returns

Purpose DumpFinalResults(1) dumps results from the current iteration for use in later iterations.

Called By main()

Calls To library functions

Local Variables

FILE *fptr input file
int c, L, P, k, i, PM, S loop variables

Global Variables

int ATPOPSIZE the number of ATPOP trunks in any give IEC
 SWITCH_SIZE the number of switches in any given IEC
Ltype OLAT
ktype OLEO
cLPtype e2
cSStype SWBlock

Algorithmic Description

DumpFinalResults() is a simple data dump. It opens the file "TAMI.finalvalues" and outputs OLAT, OLEO, SWBlock and e2. This data dump is of a format to be reread by LoadFinalValues().

Inputs	none
Outputs	
returns	no formal returns

**Algorithmic
Description**

LogResults () prints the final results of the congestion analyses to the file indicated by fptr. It also calculates summary statistics in place.

Inputs

RRctype	mtx	blockage matrix
char	name	name of summary block
FILE	* fptr	output file

Outputs

returns no formal returns

Purpose This routine formats and prints blocked traffic information to the indicated file.

Called By LogResults()

Calls To library functions

Local Variables

int	reg1, reg2
float	x

Global Variables

ctype	offdtraf
int	NUMREGIONS
	IEC_SIZE
char	IECid

Algorithmic Description

PrintBlocks() receives blocking information passed in from LogResults() and combines this blockage information with global traffic information. This information is then output to the indicated file.

Inputs

integer	* A	pointer to originating end office
	* B	pointer to terminating end office

Outputs

returns	no formal returns
---------	-------------------

Purpose	to select two random EOs form different LATAs
----------------	---

Called By	connect () psn_connect ()
------------------	------------------------------

Calls To	drandom ()	returns a random value
-----------------	------------	------------------------

**Local
Variables**

integer	lata	holds an EO lata value
double	number	holds a random number returned from drandom ()

Global Variables	RSTREAM	a random number stream
	EO_SIZE	size of the EO
	EOlata	EO to LATA connection

Algorithmic Description	SelectEO returns two EOs from different LATAs
------------------------------------	---

Inputs

integer c indicates IEC

Outputs

returns float a psn connectivity value

Purpose to determine connectivity through one IEC

Called By main()

Calls To CalcB calculates blockages
SelectEO selects two EOs from different LATAs

Local Variables

integer c loop count variable
target passed in vlaue of TargetKey[]
sum running total of number of switch pairs
count loop count variable
EOA originating end office
EOB terminating end office
flag pointer flag
idx index value
test boolean flag

double B overall blocakge
bd doc blockage
ba access blocakge
bi iec blockage
be egress blockage

float pp percentage of connectivity

Global Variables

integer TargetKey[11] target number of EO pairs
HUPOP high usage trunk to POP connectivity value
ATPOP AT to POP connectivity value
EO_SW EO to switch connectivity value

Algorithmic Description

This routine calculates a single IEC connectivity number. An EO pair is considered connected if it has connectivity through the specified IEC (c). This routine differs from psn_connect () in that it looks for connections through one IEC only.

Inputs	none	
Outputs		
returns	float	a psn connectivity value
Purpose	to determine connectivity through all IECs	
Called By	main()	
Calls To	CalcB SelectEO	
Local Variables		
integer	c	loop count variable
	target	passed in vlaue of TargetKey[]
	sum	running total of number of switch pairs
	count	loop count variable
	EOA	originating end office
	EOB	terminating end office
	flag	pointer flag
	idx	index value
	test	boolean flag
double	B	overall blocakge
	bd	doc blockage
	ba	access blocakge
	bi	iec blockage
	be	egress blockage
float	pp	percentage of connectivity
Global Variables		
integer	TargetKey[9]	target number of EO pairs
	HUPOP	high usage trunk to POP connectivity value
	ATPOP	AT to POP connnectivity value
	IEC_SIZE	size of the IEC

Algorithmic

Description This routine calculates a PSN connectivity number. An EO pair is considered connected if it has connectivity through at least one IEC. This routine differs from connect () in that it looks for connections through all IECs.

integer	c	IEC id number
---------	---	---------------

returns no formal returns

Globals:		
cSStype	SWBlock	returns the updated switch-switch blockages

Purpose For IEC c (should be AT&T), this routine converts the corresponding switch-to-switch blockage matrix (SWBLOCK) from direct-connect-only blockage to an alternate-routing blockage.

Called By `AddPriority()`

Calls To library functions

real	x1, x2, x3, x4	place holders
integer	i, j, k	loop variable
	count1, count2	
	count3, count4	

```
integer    SWalive
cSStype    SWblocknew
integer    SWITCH SIZE
```

CalCRTNR adjusts the switch-switch blockage matrix to account for RTNR. For each switch, and for each of its connections to other switches, CalCRTNR considers all available alternative routes. The appropriate adjustment between switch I and J via switch K is:

$$(1 - (1 - \text{SWBlock}[c][I][K]) * (1 - \text{SWBlock}[c][K][J])) .$$

There are appropriate sanity checks to rule out vias through dead switches, or dead origin/destination switches.

Inputs

integer c IEC id number

Outputs

returns no formal returns

Globals:

cSStype SWBlock

Purpose

This routine adds IEC trunk congestion relief (TCR) to the IEC c switch-switch blockage matrix (SWBlock).

Called By

AddPriority()

Calls To

library functions

Local Variables

real	x, sum	place holder variables
integer	i, j	loop variable
	count, count2	

Global Variables

integer SWITCH_SIZE

Algorithmic Description

Any SWBlock entry which is not 1.0 (representing 100% blockage) is changed to 0.0 (representing 0% blockage).

Inputs

integer c IEC id number

Outputs

returns no formal returns

Globals:

cSStype SWBlock

Purpose This routine alters the AT&T SWBlock matrix to reflect CSI trunks for NSEP traffic.

Called By AddPriority()

Calls To library functions

**Local
Variables**

character	line[50]	working storage
integer	a, z, surv	loop variable
	count1, count2	
FILE	* fptr	input file pointer

**Global
Variables**

character	CSIfile
integer	SWITCH_SIZE

**Algorithmic
Description**

The CSI data is loaded from the file named in CSIfile. Each record is parsed for an originating switch index (zero-based), a destination switch index, and a damage vector (0/1). If a link survives damage (1) then the SWBlock matrix between the two switches is reduced to zero (no blockage). All other blockages remain unchanged.

Inputs

short integer TCR

Outputs

returns no formal returns

Globals:kctype a3
a0
e0ktype a1
e1cLPtype a2
e2

ktype OLEO

Ltype OLAT

Purpose This routine zeros LEC blockage for all EOs in selected LATAs.**Called By** AddPriority()**Calls To** library functions**Local
Variables**

integer k, c, PM loop variable

**Global
Variables**integer EOlata
EOAT
HUPOP
ATPOP
ATPOPSIZE
IEC_SIZE
EO_SIZE**Algorithmic
Description**

CalcLECTCR zeros blockages associated with LEC facilities in the LATAs indicated by the TCR parameter. Overloads at affected EOs and ATs are also zeroed.

Inputs

integer	eoA, eob, c, reg1, reg2
long double	Bd, Ba, Bi, Be, T, B

Outputs

returns	no formal returns
---------	-------------------

Purpose	This routine writes selected results to the standard input, largely for debugging.
----------------	--

Called By	CalcBigB()
------------------	------------

Calls To	library functions
-----------------	-------------------

Local Variables

integer	s1, s2	switch indexes

kctype	AC1prime
	AC1
cStype	TRAF_DELT
	TRAF_KEEP
cSStype	SSTNG
	SSreg
	AC14adj
	AC14

Algorithmic Description	This routine does no computation; it simply prints certain statistics about an EO-EO pair.
--------------------------------	--

Inputs		
character	*infile	input file
Outputs		
returns	no formal returns	
Globals:		
real	Rmult	regional traffic multiplier
	Lmult	LATA traffic multiplier
integer	LReg	LATA to region mapping
	EOREg	EO to region mapping
Purpose	This routine loads regional information.	
Called By	main()	
Calls To	library functions print_info(void)	
Local Variables		
double	multiplier	
character	buffer1[80] , buffer2[80]	
	working memory	
integer	i,lata, region	loop variable
FILE	*inputfile	input file
Global Variables		
integer	NUMREGIONS	
	NUMEO	
	EOLata	
	EO_SIZE	
Algorithmic Description	Loadoverloads() first opens the indicated file. For each region, it then retrieves the region designation and multiplier. It then reads one line for each LATA in the region. The overload and region designation for the lata is then set. Loadoverloads() then closes the file, and sets the region for each EO.	

Inputs	none
Outputs	
returns	no formal returns
Purpose	This routine writes progress indicators to stdout.
Called By	Loadoverloads()
Calls To	library functions
Local Variables	
integer	i loop variable
Global Variables	
real	Rmult regional traffic multiplier
	Lmult LATA traffic multiplier
integer	LReg LATA to region mapping
	EOREg EO to region mapping
	NUMREGIONS
Algorithmic Description	This routine loops through all available lata and regions, printing the region/multiplier pairs.

Inputs	none
Outputs	
returns	no formal returns
Globals:	
real	RmultMatrix
Purpose	This routine generates a matrix of region to region traffic multipliers..
Called By	main()
Calls To	library functions
Local Variables	
integer	i, j loop variable
Global Variables	
real	Rmult
Algorithmic Description	This routine builds a symmetric region to region traffic multiplier matrix. The region to region traffic multiplier is taken as the max of the two regional multipliers.

Inputs

real OL the traffic overload at the switch

Outputs

real temp outgoing (access) loss at the switch

Purpose This returns the access matching loss at a switch.

Called By main()

Calls To none

**Local
Variables**

real temp

**Global
Variables**

integer MATCHOFF
HIGHMATCH
SETMATCH
real SETMATCHLEVEL

**Algorithmic
Description**

This routine determines an access matching loss based on a step-wise linear function. There are several variants available through command-line settings (-D -E -F) .

Inputs

real OL switch overload

Outputs

real temp incoming (egress) matching loss

Purpose This returns the egress matching loss at a switch.

Called By main()

Calls To none

**Local
Variables**

real temp

**Global
Variables**

integer MATCHOFF
HIGHMATCH
SETMATCH
real SETMATCHLEVEL

**Algorithmic
Description**

This routine determines an egress matching loss based on a step-wise linear function. There are several variants available through command-line settings (-D -E -F) .

Inputs

integer	eoA, eob	IEC id number
	c	returns error indicator flag
	*flag	returns overall blockage
double	*b	returns blockage due to DOC
	*bd	returns access blockage
	*ba	returns IEC blockage
	*bi	returns egress blockage
	*be	

Outputs

returns no formal returns

the following are used to determine DOC levels

Algorithmic Description

CalcB calculates EO to EO total blockage. It first determines the LEC to IEC topology, adjusting for damage. If the EOs in question are not connected to each other, 1.0 is returned for all blockages and the flag variable is set appropriately. Globally available blockage figures are then combined appropriately to yield access, egress and IEC blockages. These are then combined to determine overall blockage.

Inputs

RRctype	BigB	returns blockages
integer	c	IEC id number
integer	TRAFMAT	flag indicating whether or not a traffic matrix has been provided

Outputs

returns no formal returns

Purpose This routine uses statistical sampling to estimate the overall EO-EO blockage, based on minimal EO pairs.

Called By main()
AddPriority()

Calls To library functions

Algorithmic Description

CalcBigB uses statistical sampling to estimate traffic-weighted EO-EO blockage. If a traffic matrix is given, CalcBigB calls GetEOandT() to retrieve EOs and traffic values. If no traffic matrix is given, it randomly determines EOs to sample, and uses CalcT() to determine the traffic between the selected EOs. This sampling is performed for each region-region pair. The EO pairs are sorted into bins based on traffic values, in order to decrease the probability of rounding inaccuracy. Each bin has an initial target number. Sampling continues until the bin target has been met, or the available EOs are exhausted. At this point, a number of statistics are determined for the sample, including mean, standard deviation and error. If the error is not within acceptable bounds (currently hardcoded at 3 percent), further sampling is performed. The final blockage values are returned in the BigB argument.

Inputs	none
Outputs	
returns	no formal returns
Globals: from calcbigb.c	
struct pair	eopair
Purpose	This routine loads a traffic matrix from the file indicated by the variable nij_file.
Called By	CalcBigB()
Calls To	library functions TrafBin()
Local Variables	
integer	i, count
character	line[80]
FILE	*nijptr

	ACSlec_live
kc2type	F0

**Algorithmic
Description**

CalcT() determines the POTS traffic between eoa and eob which is carried on IEC c. It first determines the topology of the given EOs, and their connectivity. If they are not sufficiently connected based on the scenario under consideration (EARLY or LATE), Tij is set to 1.0 and flag is set. Otherwise, the overload multiplier is set based on the already determined regional and global overloads. Based on the scenario under consideration the F0 traffic is modified appropriately, and returned in Tij.

Inputs

integer	*EOA, *EOB	returns the selected EOs
integer	c	the carrier to which the EOs must be homed
integer	regA, regB	the regions from which to select EOs

Outputs

returns	no formal returns
---------	-------------------

Purpose This routine randomly selects a pair of EOs from different LATAs, fulfilling regional and carrier homing restrictions.

Called By CalcBigB()

Calls To library functions

Local Variables

double	rnumber	holder for random number
integer	n	holds the lata number of EOA
	stream -15	the random number stream to be used

Global Variables

integer	RSTREAM
	EOLata
from calcbigb.c	
integer	reg1_eolist, reg1_tot
	reg2_eolist, reg2_tot

Algorithmic Description

SelectEOReg() iteratively picks random EOs from the global reg1_eolist and reg2_eolist until the conditions are met. The EOs are returned through *EOA and *EOB.

Inputs	none
Outputs	
returns	no formal returns
Globals:	
real	CONNpsn_rtnr CONNpsn_csi
ctype	CONNrtnr CONNcsi
RRctype	BigBrtnr0 BigBrtnr1 BigBcsi BigBtcr0 BigBtcr1 BigBlec0 BigBlec1
Purpose	This routine calculates final blockages after priority treatments.
Called By	main()
Calls To	library functions CountEOPairs() CalcRTNR() CalcCSI() CalcTCR() CalcLECTCR()
Local Variables	
integer	c, i
Global Variables	
integer	COUNTPAIRS attnum RSTREAM IEC_SIZE DOC NSEPMAT CSI LECTCR
character	IECid
Algorithmic Description	AddPriority() calculates cumulative benefits from priority treatments. Because CalcRTNR(), CalcCSI(), etc. alter the SWBlock matrix, all calculations are cumulative. Each block of the function calculates an additional enhancement by calling the appropriate Calc* function to change the SWBlock matrix, then rerunning CalcBigB() - perhaps once for each carrier. If a traffic matrix is available, the blockages are also calculated using weighting from the provided traffic matrix.

Inputs

long integer bins

Outputs

returns no formal returns

Globals:

ctype offdtraffic

Purpose

This routine checks connectivity of all EO pairs through each IEC.

Called By

AddPriority()

Calls To

library functions

**Local
Variables**

double B
 w, x, y, z

integer EOA, EOB
 i, c, flag

long integer count

**Global
Variables**

integer IEC_SIZE
 EOlata
 EOalive
 EO_SIZE

**Algorithmic
Description**

For all possible pairs of end offices, their connectivity is assessed through each of the three IECs. CountEOPairs() uses CalcB() to determine connectivity between each pair, and prints aggregate statistics to stdout.

3.12 keepstats: Record Overall Statistics

Purpose This program accumulates TAMI blockage statistics over a number of iterations by maintaining a statistics file. The input statistics for each iteration are given by an input file. This program will accumulate statistics for each variable in the input file.

Call Syntax

<code>keepstats</code>	<code>[options]</code>	
<i>mandatory:</i>	<i>special syntax:</i>	<i>function:</i>
none		
<i>options:</i>	<i>special syntax:</i>	<i>function:</i>
-k	<input filename>	reads in input file name, if not specified, default file name is TAMI.lecamlog
-o	<outfile>	reads in output file name, if not specified, default file name is TAMI.tally
-O		indicates overwriting of output file
-?		user help--prints call syntax and exits without running

example `keepstats -k keyfile -O`

Input

Files TAMI.lecamlog this file contains output data from the lecam.c module

format SEE SECTION 3. 11/lecam.c module

Output

Files outfile The output file for keepstats consists of 8 sections which report various blockage calculations and 1 section which reports connectivity. For each iteration, sums are given for the following blockage values for:

- accumulated sums of blockage
- accumulated sums of blockages squared
- number of damage vectors
- accumulated mean blocking sum
- standard deviation
- error rate

section1: POTS <POTS blockage for each iec, iec = att, mci, spr>

section2: SAMP <Regional sampling of POTS for 2 regions, '0' and '1' for each iec, iec = att, mci, spr>

section3: RTNR0 <NSEP traffic with RTNR and DOC off, with POTS weighting for 2 regions, '0' and '1' for each iec, iec = att, mci, spr>

section4: RTNR1 <NSEP traffic with RTNR and DOC off, with NSEP traffic weighting for 2 regions, '0' and '1' for each iec, iec = att, mci, spr>

section5: TCR0 <NSEP traffic with TCR and DOC off, with POTS weighting for 2 regions, '0' and '1' for each iec, iec = att, mci, spr>

	section6: TCR1	<NSEP traffic with TCR and DOC off, with NSEP traffic weighting for 2 regions,'0' and '1' for each iec, iec = att, mci, spr>
	section7: LEC0	<LEC traffic with DOC off, with POTS weighting for 2 regions,'0' and '1' for each iec, iec = att, mci, spr>
	section8: LEC1	<LEC traffic with DOC off, with NSEP traffic weighting for 2 regions,'0' and '1' for each iec, iec = att, mci, spr>
Includes	"fileio.c" <stdio.h> <math.h>	User-defined I/O functions; see Appendix A The standard 'C' I/O functions. The standard 'C' math functions.

Component Functions	LoadStats ()	reads existing output file and loads value into the record structure.
	AddStats ()	sums output statistics.

Function Tree

Algorithmic Description

This module is used to print to an outfile, file various TAMI blockage statistics. This program accumulates TAMI blockage statistics over a number of iterations by maintaining a stats file called TAMI.tally (unless a different stats file is given by the command line). The input stats for each iteration are given by a file named TAMI.lecamlog (or other as specified). This program will accumulate stats for each variable in the input file. The variable names must begin with 'BIGB' and be followed immediately by an equal sign and the blockage for that variable, e.g.:

**BIGBPOTS=0.12345 or
BIGBatt=0.987655**

If an entry in the output file does not already exist for a given variable, then one will be created.

The output file contains the following: var name, sum of blockages, sum of blockages squared, the number of iterations accumulated, the mean blockage, standard deviation, and error. The error for BIGBPOTS will be written to the screen for output back to the shell script.

Std.Dev. Formula:

$$S = \sqrt{\frac{TBS - (M^2 * N)}{N - 1}}$$

where TBS is the total blockage squared, N is the sample size, and M is the sample mean.

Error Formula:

$$E = \frac{T(N - 1, C) * S}{\sqrt{N}}$$

where S is the sample standard deviation, N is the sample size, and T is the value of the T-distribution for N-1 and confidence level C. (The data for the T-dist is loaded for N-1 up to 30 and C=95%.

Inputs

character * fptr pointer to an input file

Outputs

structure StatList of type records
with fields

character varname[30] the name of the variable being tallied

real sum sum of blockage
sumsq sum of blockage-squared
mean mean blockage
sdev standard deviation of blockage
error sampling error

integer iter number of iterations tallied

returns this module returns the value of i, the number of variables in the Tally file

Purpose For each variable in the input file, this function loads the variable value into the StatList structure.

Called By main()

Calls To none

Local Variables

integer i loop count variable

Global Variables none

Global Constants MAXVAR maximum number of variables expected from input file

Algorithmic Description

For each variable in the input file, this function loads the variable value into the StatList structure. It also counts the variables to ensure that they don't exceed MAXVAR.

Inputs

integer	*numvars	pointer to the number of variables
character	name[]	temporarily holds a variable name
real	B	blocking probability

Outputs

structure	StatList of type records with fields	
character	varname[30]	the name of the variable being tallied
real	sum	sum of blockage
	sumsqr	sum of blockage-squared
	mean	mean blockage
	sdev	standard deviation of blockage
	error	sampling error
integer	iter	number of iterations tallied
returns	integer	

Purpose For each variable in the StatList structure, this function adds the next value of that variable to the existing value.

Called By main()

Calls To none

Local Variables

integer i, j loop count variables

Global Variables none

Global Constants none

Algorithmic Description For each variable in the StatList structure, this function adds the next value of that variable to the existing value, thus accumulating a total output file.

Appendix A: User-Defined Utility Functions

Functions that are repeatedly utilized by more than one module have been placed in this appendix in order to make them readily available. These “utility” functions are divided into two groups:

1) Function calls repeatedly coded into various modules

```
fget()  
char_comp()
```

2) Function calls included in include “fileio.c”, “traffic.c”, and “poisson.c”:

```
fileio.c  
  parse()  
  parse_int()  
  getline()  
  fopenfile()
```

```
traffic.c  
  ErlangA()  
  ErlangB()  
  ErlangN()  
  PoissonA()  
  PoissonB()  
  PoissonN()
```

```
poisson.c  
  PoissonAmod()  
  PoissonNmod()
```

```
phdiv.c  
  phdiv()
```

Appendix A: User-Defined Utility Functions

Functions that are repeatedly utilized by more than one module have been placed in this appendix in order to make them readily available. These “utility” functions are divided into two groups:

- 1) Function calls repeatedly coded into various modules

```
fget()  
char_comp()
```

- 2) Function calls included in include “fileio.c”, “traffic.c”, and “poisson.c”:

```
fileio.c  
  parse()  
  parse_int()  
  getline()  
  fopenfile()  
  
traffic.c  
  ErlangA()  
  ErlangB()  
  ErlangN()  
  PoissonA()  
  PoissonB()  
  PoissonN()  
  
poisson.c  
  PoissonAmod()  
  PoissonNmod()  
  
phdiv.c  
  phdiv()
```

file	*fopenfile(filename, type)	fileio.c
This utility function is a simple modification of the standard 'C' <code>fopen</code> function. It opens the passed in filename and checks for an error in the file. If an error exists the function is exited.		
void	parse(start, num, buffer, rtn)	fileio.c
This utility function reads <code>num</code> characters from the input character string <code>buffer</code> starting at position <code>start</code> and directs the output to the character string <code>rtn</code> .		
int	parse_int(start, num, buffer)	fileio.c
This utility function reads <code>num</code> characters from the input character string <code>buffer</code> starting at position <code>start</code> and returns the integer value of the characters		
int	getline(fildes, buf)	fileio.c
This utility function reads from the file <code>fildes</code> until the first end-of-line character is reached, and directs the output to the buffer <code>buf</code>		
double	ErlangA(double Bin, int N)	traffic.c
This utility function calculates the amount of offered traffic given an ErlangB blocking probability <code>Bin</code> , and a trunk size <code>N</code> .		
double	ErlangB(double A, int N)	traffic.c
This utility function uses ErlangB statistics to calculate a blocking probability given trunk size <code>N</code> , and the amount of offered traffic <code>A</code> .		
int	ErlangN(double A, double Bin)	traffic.c
This utility function calculates trunk size given an Erlang B blocking probability <code>Bin</code> , and the amount of offered traffic <code>A</code> .		
double	PoissonA(double Bin, int N)	traffic.c
This utility function calculates offered traffic given a Poisson blocking probability <code>Bin</code> , and the number of trunks <code>N</code> .		
double	PoissonB(double A, int N)	traffic.c
This utility function uses Poisson statistics to calculate a blocking probability given trunk size <code>N</code> , and the amount of offered traffic <code>A</code> .		
double	PoissonN(double A, double Bin)	traffic.c
This utility function calculates the number of trunks, given a Poisson blocking probability <code>Bin</code> , and the amount of offered traffic <code>A</code> .		

double PoissonAmod(double Bin, int Nin)

poisson.c

This utility function Calculates offered traffic given a Poisson blocking probability Bin, and the number of trunks Nin. It is a "reality" modification of the PoissonA routine. It is based on the assumption that TGs with more than 250 trunks are engineered for traffic levels proportional to the level for exactly 250 trunks. Traffic in TGs with fewer than 250 trunks is calculated normally with the PoissonA routine. Two traffic constants have been precalculated for this routine. A005 and A01 represent the traffic levels through 250 trunks which produce blockages of 0.005 and 0.01 respectively.

double PoissonNmod(double Ain, double Bin)

poisson.c

This utility function calculates the number of trunks, give a Poisson blocking probability Bin, and the amount of offered traffic Ain. It is a "reality" modification of the PoissonN routine. It is based on the assumption that TGs with more than 250 trunks are engineered for traffic levels proportional to the level for exactly 250 trunks. Traffic in TGs with fewer than 250 trunks is calculated normally with the PoissonN routine. Two traffic constants have been precalculated for this routine. A005 and A01 represent the traffic levels through 250 trunks which produce blockages of 0.005 and 0.01 respectively.

int phdiv(eo,at,pop)

phdiv.c

This utility function performs the physical diversity model. It returns a 1 (TRUE) if the soecified EO-AT-POP trunk group is physically diverse from the parallel EO-AT-POP trunk group. Otherwise it returns a 0 (FALSE)

Appendix B: keyfile

This appendix contains samples of the key files used to execute a typical run of the TAMI program.
